## Hierarchy For All Packages

### Package Hierarchies:

com.sun.media.jai.codec, javax.media.jai, javax.media.jai.iterator, javax.media.jai.operator, javax.media.jai.widget

---

### Class Hierarchy

- class java.lang.Object
  - class javax.media.jai.operator.**AffinePropertyGenerator** (implements javax.media.jai.PropertyGenerator)
  - class com.sun.media.jai.codec.**BMPEncodeParam** (implements com.sun.media.jai.codec.ImageEncodeParam)
  - class javax.media.jai.**BorderExtender**
    - class javax.media.jai.**BorderExtenderConstant**
    - class javax.media.jai.**BorderExtenderCopy**
    - class javax.media.jai.**BorderExtenderReflect**
    - class javax.media.jai.**BorderExtenderWrap**
    - class javax.media.jai.**BorderExtenderZero**
  - class javax.media.jai.**CollectionImage** (implements java.util.Collection, javax.media.jai.ImageJAI)
    - class javax.media.jai.**CollectionOp**
    - class javax.media.jai.**ImageSequence**
    - class javax.media.jai.**ImageStack**
  - class java.awt.image.ColorModel (implements java.awt.Transparency)
    - class java.awt.image.ComponentColorModel
      - class javax.media.jai.**FloatDoubleColorModel**
  - class java.awt.Component (implements java.awt.image.ImageObserver, java.awt.MenuContainer, java.io.Serializable)
    - class java.awt.Canvas
      - class javax.media.jai.**CanvasJAI**
      - class javax.media.jai.widget.**ImageCanvas**
    - class java.awt.Container
      - class java.awt.ScrollPane
        - class javax.media.jai.widget.**ScrollingImagePanel** (implements java.awt.event AdjustmentListener, java.awt.event.ComponentListener, java.awt.event.MouseListener, java.awt.event.MouseMotionListener)
  - class javax.media.jai.operator.**ConjugatePropertyGenerator** (implements javax.media.jai.PropertyGenerator)
  - class javax.media.jai.**CoordinateImage**
  - class javax.media.jai.**CopyPropertyGenerator** (implements javax.media.jai.PropertyGenerator)
  - class java.awt.image.DataBuffer
    - class javax.media.jai.**DataBufferDouble**
    - class javax.media.jai.**DataBufferFloat**
  - class javax.media.jai.operator.**DFTPropertyGenerator** (implements javax.media.jai.PropertyGenerator)
  - class javax.media.jai.operator.**DivideComplexPropertyGenerator** (implements javax.media.jai.PropertyGenerator)
  - class com.sun.media.jai.codec.**FPXDecodeParam** (implements com.sun.media.jai.codec.ImageDecodeParam)
  - class java.awt.Graphics
    - class java.awt.Graphics2D
      - class javax.media.jai.**GraphicsJAI**
      - class javax.media.jai.**RenderableGraphics** (implements java.awt.image.renderable.RenderableImage)
      - class javax.media.jai.**TiledImageGraphics**
  - class javax.media.jai.**Histogram** (implements java.io.Serializable)
  - class javax.media.jai.operator.**IDFTPropertyGenerator** (implements javax.media.jai.PropertyGenerator)
  - class com.sun.media.jai.codec.**ImageCodec**
  - class com.sun.media.jai.codec.**ImageDecoderImpl** (implements com.sun.media.jai.codec.ImageDecoder)
  - class com.sun.media.jai.codec.**ImageEncoderImpl** (implements com.sun.media.jai.codec.ImageEncoder)
  - class javax.media.jai.operator.**ImageFunctionPropertyGenerator** (implements javax.media.jai.PropertyGenerator)
  - class javax.media.jai.**ImageLayout** (implements java.lang.Cloneable, java.io.Serializable)
  - class javax.media.jai.**ImageMIPMap** (implements javax.media.jai.ImageJAI)
    - class javax.media.jai.**ImagePyramid**
  - class java.io.InputStream
    - class com.sun.media.jai.codec.**SeekableStream** (implements java.io.DataInput)
      - class com.sun.media.jai.codec.**ByteArraySeekableStream**
      - class com.sun.media.jai.codec.**FileCacheSeekableStream**
      - class com.sun.media.jai.codec.**FileSeekableStream**
      - class com.sun.media.jai.codec.**ForwardSeekableStream**

- class com.sun.media.jai.codec.**MemoryCacheSeekableStream**
  - class com.sun.media.jai.codec.**SegmentedSeekableStream**
- class javax.media.jai.**IntegerSequence**
- class javax.media.jai.**Interpolation** (implements java.io.Serializable)
  - class javax.media.jai.**InterpolationBilinear**
  - class javax.media.jai.**InterpolationNearest**
  - class javax.media.jai.**InterpolationTable**
    - class javax.media.jai.**InterpolationBicubic**
    - class javax.media.jai.**InterpolationBicubic2**
- class javax.media.jai.**JAI**
- class javax.media.jai.**Jai18N**
- class javax.media.jai.iterator.**Jai18N**
- class javax.media.jai.operator.**Jai18N**
- class javax.media.jai.widget.**Jai18N**
- class com.sun.media.jai.codec.**Jai18N**
- class com.sun.media.jai.codec.**JPEGEncodeParam** (implements com.sun.media.jai.codec.ImageEncodeParam)
- class javax.media.jai.**KernelJAI** (implements java.io.Serializable)
- class javax.media.jai.**LookupTableJAI** (implements java.io.Serializable)
  - class javax.media.jai.**ColorCube**
- class javax.media.jai.operator.**MagnitudePropertyGenerator** (implements javax.media.jai.PropertyGenerator)
- class javax.media.jai.operator.**MagnitudeSquaredPropertyGenerator** (implements javax.media.jai.PropertyGenerator)
- class javax.media.jai.operator.**MultiplyComplexPropertyGenerator** (implements javax.media.jai.PropertyGenerator)
- class javax.media.jai.**MultiResolutionRenderableImage** (implements java.awt.image.renderable.RenderableImage, java.io.Serializable)
- class javax.media.jai.**NoParameterDefault**
- class javax.media.jai.**OperationDescriptorImpl** (implements javax.media.jai.OperationDescriptor)
  - class javax.media.jai.operator.**AbsoluteDescriptor**
  - class javax.media.jai.operator.**AddCollectionDescriptor**
  - class javax.media.jai.operator.**AddConstDescriptor**
  - class javax.media.jai.operator.**AddConstToCollectionDescriptor**
  - class javax.media.jai.operator.**AddDescriptor**
  - class javax.media.jai.operator.**AffineDescriptor**
  - class javax.media.jai.operator.**AndConstDescriptor**
  - class javax.media.jai.operator.**AndDescriptor**
  - class javax.media.jai.operator.**AWTImageDescriptor**
  - class javax.media.jai.operator.**BandCombineDescriptor**
  - class javax.media.jai.operator.**BandSelectDescriptor**
  - class javax.media.jai.operator.**BMPDescriptor**
  - class javax.media.jai.operator.**BorderDescriptor**
  - class javax.media.jai.operator.**BoxFilterDescriptor**
  - class javax.media.jai.operator.**ClampDescriptor**
  - class javax.media.jai.operator.**ColorConvertDescriptor**
  - class javax.media.jai.operator.**CompositeDescriptor**
  - class javax.media.jai.operator.**ConjugateDescriptor**

## Package javax.media.jai

Interface Summary	
<b><i>CollectionImageFactory</i></b>	The <code>CollectionImageFactory</code> interface (often abbreviated CIF) is intended to be implemented by classes that wish to act as factories to produce different collection image operators.
<b><i>ImageFunction</i></b>	<code>ImageFunction</code> is a common interface for vector-valued functions which are to be evaluated at positions in the X-Y coordinate system.
<b><i>ImageJAI</i></b>	An interface implemented by all JAI image classes.
<b><i>OperationDescriptor</i></b>	This interface provides a comprehensive description of a specific image operation.
<b><i>PropertyGenerator</i></b>	An interface through which properties may be computed dynamically with respect to an environment of pre-existing properties.
<b><i>PropertySource</i></b>	An interface encapsulating the set of operations involved in identifying and reading properties.
<b><i>TileCache</i></b>	A class implementing a caching mechanism for image tiles.
<b><i>TileScheduler</i></b>	A class implementing a mechanism for scheduling tile calculation.

Class Summary	
<b><i>AreaOpImage</i></b>	An abstract base class for image operators that require only a fixed rectangular source region around a source pixel in order to compute each destination pixel.
<b><i>BorderExtender</i></b>	An abstract superclass for classes that extend a <code>WritableRaster</code> with additional pixel data taken from a <code>PlanarImage</code> .
<b><i>BorderExtenderConstant</i></b>	A subclass of <code>BorderExtender</code> that implements border extension by filling all pixels outside of the image bounds with constant values.
<b><i>BorderExtenderCopy</i></b>	A subclass of <code>BorderExtender</code> that implements border extension by filling all pixels outside of the image bounds with copies of the edge pixels.
<b><i>BorderExtenderReflect</i></b>	A subclass of <code>BorderExtender</code> that implements border extension by filling all pixels outside of the image bounds with copies of the whole image.
<b><i>BorderExtenderWrap</i></b>	A subclass of <code>BorderExtender</code> that implements border extension by filling all pixels outside of the image bounds with copies of the whole image.
<b><i>BorderExtenderZero</i></b>	A subclass of <code>BorderExtender</code> that implements border extension by filling all pixels outside of the image bounds with zeros.
<b><i>CanvasJAI</i></b>	An extension of <code>java.awt.Canvas</code> for use with JAI.
<b><i>CollectionImage</i></b>	An abstract superclass for classes representing a collection of images.
<b><i>CollectionOp</i></b>	A node in either a rendered or a renderable image chain representing a <code>CollectionImage</code> .
<b><i>ColorCube</i></b>	A subclass of <code>LookupTableJAI</code> which represents a lookup table which is a color cube.
<b><i>ComponentSampleModelJAI</i></b>	This class represents image data which is stored such that each sample of a pixel occupies one data element of the <code>DataBuffer</code> .
<b><i>CoordinateImage</i></b>	A class representing an image that is associated with a coordinate.
<b><i>CopyPropertyGenerator</i></b>	Copy properties from a <code>PlanarImage</code> rendering.
<b><i>DataBufferDouble</i></b>	An extension of <code>DataBuffer</code> that stores data internally in <code>double</code> form.
<b><i>DataBufferFloat</i></b>	An extension of <code>DataBuffer</code> that stores data internally in <code>float</code> form.

<b>FloatDoubleColorModel</b>	A <code>ColorModel</code> class that works with pixel values that represent color and alpha information as separate samples, using float or double elements.
<b>GraphicsJAI</b>	A JAI wrapper for a <code>Graphics2D</code> object derived from a <code>Component</code> .
<b>Histogram</b>	An object for accumulating histogram information on an image.
<b>ImageLayout</b>	A class describing the desired layout of an <code>OpImage</code> .
<b>ImageMIPMap</b>	A class implementing the "MIP map" operation on a <code>RenderedImage</code> .
<b>ImagePyramid</b>	A class implementing the "Pyramid" operation on a <code>RenderedImage</code> .
<b>ImageSequence</b>	A class representing a sequence of images, each associated with a time stamp and a camera position.
<b>ImageStack</b>	A class representing a stack of images, each associated with a spatial orientation defined in a common coordinate system.
<b>IntegerSequence</b>	A growable sorted integer set.
<b>Interpolation</b>	An object encapsulating a particular algorithm for image interpolation (resampling).
<b>InterpolationBicubic</b>	A class representing bicubic interpolation.
<b>InterpolationBicubic2</b>	A class representing bicubic interpolation using a different polynomial than <code>InterpolationBicubic</code> .
<b>InterpolationBilinear</b>	A class representing bilinear interpolation.
<b>InterpolationNearest</b>	A class representing nearest-neighbor interpolation.
<b>InterpolationTable</b>	A subclass of <code>Interpolation</code> that uses tables to store the interpolation kernels.
<b>JAI</b>	A convenience class for instantiating operations.
<b>JAI.RenderingKey</b>	Rendering hints.
<b>JaiI18N</b>	
<b>KernelJAI</b>	A kernel, used by the <code>Convolve</code> , <code>Ordered Dither</code> , and <code>Error Diffusion</code> operations.
<b>LookupTableJAI</b>	A lookup table object associated with the "Lookup" operation.
<b>MultiResolutionRenderableImage</b>	A <code>RenderableImage</code> that produces renderings based on a set of supplied <code>RenderedImage</code> s at various resolutions.
<b>NoParameterDefault</b>	A class that signifies that a parameter has no default value.
<b>NullOpImage</b>	A trivial <code>OpImage</code> subclass that simply transmits its source unchanged.
<b>OperationDescriptorImpl</b>	This class provides a concrete implementation of the <code>OperationDescriptor</code> interface, and is suitable for subclassing.
<b>OperationGraph</b>	<code>OperationGraph</code> manages a list of products belonging to a particular operation descriptor.
<b>OperationRegistry</b>	A class implementing the translation of operation names into instances of <code>RenderedImageFactory</code> , <code>ContextualRenderedImageFactory</code> and <code>CollectionImageFactory</code> .
<b>OpImage</b>	The parent class for all imaging operations.
<b>ParameterBlockJAI</b>	A convenience subclass of <code>ParameterBlock</code> that allows the use of default parameter values and getting/setting parameters by name.
<b>PartialOrderNode</b>	A node in a directed graph of operations.
<b>PerspectiveTransform</b>	A 2D perspective (or projective) transform, used by various <code>OpImages</code> .
<b>PlanarImage</b>	The fundamental base class representing two-dimensional images.

<b>PointOpImage</b>	An abstract base class for image operators that require only the (x, y) pixel from each source image in order to compute the destination pixel (x, y).
<b>ProductOperationGraph</b>	ProductOperationGraph manages a list of operations (image factories) belonging to a particular product.
<b>PropertyGeneratorFromSource</b>	A class that implements the PropertyGenerator interface.
<b>PropertySourceImpl</b>	A class that implements the PropertySource interface.
<b>RasterAccessor</b>	An adapter class for presenting image data in a ComponentSampleModel format, even if the data isn't stored that way.
<b>RasterFactory</b>	A convenience class for the construction of various types of WritableRaster and SampleModel objects.
<b>RasterFormatTag</b>	This class encapsulates the information needed for RasterAccessor to understand how a Raster is laid out.
<b>RegistryInitData</b>	
<b>RemoteImage</b>	A sub-class of PlanarImage which represents an image on a remote server machine.
<b>RenderableGraphics</b>	An implementation of Graphics2D with RenderableImage semantics.
<b>RenderableImageAdapter</b>	An adapter class for externally-generated RenderableImages.
<b>RenderableOp</b>	A JAI version of RenderableImageOp.
<b>RenderedImageAdapter</b>	A PlanarImage wrapper for a non-writable RenderedImage.
<b>RenderedOp</b>	A node in a rendered imaging chain.
<b>ROI</b>	The parent class for representations of a region of interest of an image.
<b>ROIShape</b>	A class representing a region of interest within an image as a Shape.
<b>ScaleOpImage</b>	A class extending WarpOpImage for use by further extension classes that perform image scaling.
<b>SequentialImage</b>	A class representing an image that is associated with a time stamp and a camera position.
<b>Snapshot</b>	A non-public class that holds a portion of the state associated with a SnapshotImage.
<b>SnapshotImage</b>	A class providing an arbitrary number of synchronous views of a possibly changing WritableRenderedImage.
<b>SnapshotProxy</b>	A proxy for Snapshot that calls Snapshot.dispose() when finalized.
<b>SourcelessOpImage</b>	An abstract base class for image operators that have no image sources.
<b>StatisticsOpImage</b>	An abstract base class for image operators that compute statistics on a given region of an image, and with a given sampling rate.
<b>Storage</b>	
<b>Store</b>	
<b>TileCopy</b>	A (Raster, X, Y) tuple.
<b>TiledImage</b>	A concrete implementation of WritableRenderedImage.
<b>TiledImageGraphics</b>	A concrete (i.e., non-abstract) class implementing all the methods of Graphics2D (and thus of Graphics) with a TiledImage as the implicit drawing canvas.
<b>UntiledOpImage</b>	A general class for single-source operations in which the values of all pixels in the source image contribute to the value of each pixel in the destination image.
<b>Warp</b>	A description of an image warp.

<b>WarpAffine</b>	A description of an Affine warp.
<b>WarpCubic</b>	A cubic-based description of an image warp.
<b>WarpGeneralPolynomial</b>	A general polynomial-based description of an image warp.
<b>WarpGrid</b>	A regular grid-based description of an image warp.
<b>WarpOpImage</b>	A general implementation of image warping, and a superclass for other geometric image operations.
<b>WarpPerspective</b>	A description of a perspective (projective) warp.
<b>WarpPolynomial</b>	A polynomial-based description of an image warp.
<b>WarpQuadratic</b>	A quadratic-based description of an image warp.
<b>WritableRasterJAI</b>	
<b>WritableRenderedImageAdapter</b>	A <code>PlanarImage</code> wrapper for a <code>WritableRenderedImage</code> .

## javax.media.jai Class AreaOpImage

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|   |
|   +-- javax.media.jai.OpImage
|       |
|       +-- javax.media.jai.AreaOpImage
```

---

public abstract class **AreaOpImage**  
extends OpImage

An abstract base class for image operators that require only a fixed rectangular source region around a source pixel in order to compute each destination pixel.

The source and the destination images will occupy the same region of the plane. A given destination pixel (x, y) may be computed from the neighborhood of source pixels beginning at (x - leftPadding, y - topPadding) and extending to (x + rightPadding, y + bottomPadding) inclusive.

Since this operator needs a region around the source pixel in order to compute the destination pixel, the border destination pixels cannot be computed without any source extension. The source extension can be specified by supplying a BorderExtender that will define the pixel values of the source outside the actual source area.

If no extension is specified, the destination samples that cannot be computed will be written in the destination as zero. If the source image begins at pixel (minX, minY) and has width w and height h, the result of performing an area operation will be an image beginning at minX, minY, and having a width of w and a height of h, with the area being computed and written starting at (minX + leftPadding, minY + topPadding) and having width Math.max(w - leftPadding - rightPadding, 0) and height Math.max(h - topPadding - bottomPadding, 0).

**See Also:**

BorderExtender

---

### Field Detail

#### leftPadding

protected int **leftPadding**

The number of source pixels needed to the left of the central pixel.

---

#### rightPadding

protected int **rightPadding**

The number of source pixels needed to the right of the central pixel.

---

#### topPadding

protected int **topPadding**

The number of source pixels needed above the central pixel.

---

#### bottomPadding

protected int **bottomPadding**

The number of source pixels needed below the central pixel.

---

#### extender

protected BorderExtender **extender**

The BorderExtender, may be null.

---

## theDest

private java.awt.Rectangle **theDest**

## Constructor Detail

### AreaOpImage

```
public AreaOpImage(java.awt.image.RenderedImage source,  
                   BorderExtender extender,  
                   TileCache cache,  
                   ImageLayout layout,  
                   int leftPadding,  
                   int rightPadding,  
                   int topPadding,  
                   int bottomPadding,  
                   boolean cobbleSources)
```

Constructs an AreaOpImage. The output min X, min Y, width, and height are copied from the source image. The SampleModel and ColorModel of the output are set in the standard way by the OpImage constructor.

Additional control over the image bounds, tile grid layout, SampleModel, and ColorModel may be obtained by specifying an ImageLayout parameter. This parameter will be passed to the superclass constructor unchanged.

#### Parameters:

source - A RenderedImage.  
extender - A BorderExtender, or null.  
cache - a TileCache object to store tiles from this OpImage, or null. If null, a default cache will be used.  
layout - An ImageLayout containing the source dimensions before padding, and optionally containing the tile grid layout, SampleModel, and ColorModel.  
leftPadding - The desired left padding.  
rightPadding - The desired right padding.  
topPadding - The desired top padding.  
bottomPadding - The desired bottom padding.  
cobbleSources - A boolean indicating whether computeRect() expects contiguous sources.

#### Throws:

java.lang.IllegalArgumentException - if combining the intersected source bounds with the layout parameter results in negative output width or height.

## Method Detail

### getLeftPadding

```
public int getLeftPadding()
```

Returns the number of pixels needed to the left of the central pixel.

#### Returns:

The left padding factor.

### getRightPadding

```
public int getRightPadding()
```

Returns the number of pixels needed to the right of the central pixel.

#### Returns:

The right padding factor.

### getTopPadding

```
public int getTopPadding()
```

Returns the number of pixels needed above the central pixel.

#### Returns:

The top padding factor.

### getBottomPadding

```
public int getBottomPadding()
```

Returns the number of pixels needed below the central pixel.

#### Returns:

The bottom padding factor.

---

## mapSourceRect

```
public java.awt.Rectangle mapSourceRect(java.awt.Rectangle sourceRect,  
                                         int sourceIndex)
```

Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**Parameters:**

sourceRect - the Rectangle in source coordinates.  
sourceIndex - the index of the source image.

**Returns:**

a Rectangle indicating the potentially affected destination region, or null if the region is unknown.

**Throws:**

java.lang.IllegalArgumentException - if sourceIndex is negative or greater than the index of the last source.  
NullPointerException - if sourceRect is null.

**Overrides:**

mapSourceRect in class OpImage

---

## mapDestRect

```
public java.awt.Rectangle mapDestRect(java.awt.Rectangle destRect,  
                                       int sourceIndex)
```

Returns a conservative estimate of the region of a specified source that is required in order to compute the pixels of a given destination rectangle.

**Parameters:**

destRect - the Rectangle in destination coordinates.  
sourceIndex - the index of the source image.

**Returns:**

a Rectangle indicating the required source region.

**Throws:**

java.lang.IllegalArgumentException - if sourceIndex is negative or greater than the index of the last source.  
NullPointerException - if destRect is null.

**Overrides:**

mapDestRect in class OpImage

---

## computeTile

```
public java.awt.image.Raster computeTile(int tileX,  
                                          int tileY)
```

Computes a tile. If source cobbling was requested at construction time, the source tile boundaries are overlayed onto the destination, cobbling is performed for areas that intersect multiple source tiles, and `computeRect(Raster[], WritableRaster, Rectangle)` is called for each of the resulting regions. Otherwise, `computeRect(PlanarImage[], WritableRaster, Rectangle)` is called once to compute the entire active area of the tile.

The image bounds may be larger than the bounds of the source image. In this case, samples for which there are no no corresponding sources are set to zero.

**Parameters:**

tileX - The X index of the tile.  
tileY - The Y index of the tile.

**Returns:**

The tile as a Raster.

**Overrides:**

computeTile in class OpImage

---

## javax.media.jai Class BorderExtender

java.lang.Object  
|  
+-- javax.media.jai.BorderExtender

### Direct Known Subclasses:

BorderExtenderConstant, BorderExtenderCopy, BorderExtenderReflect, BorderExtenderWrap, BorderExtenderZero

---

public abstract class **BorderExtender**  
extends java.lang.Object

An abstract superclass for classes that extend a `WritableRaster` with additional pixel data taken from a `PlanarImage`. Instances of `BorderExtender` are used by the `getExtendedData()` and `copyExtendedData()` methods in `PlanarImage`.

Each instance of `BorderExtender` has an `extend()` method that takes a `WritableRaster` and a `PlanarImage`. The portion of the raster that intersects the bounds of the image will already contain a copy of the image data. The remaining area is to be filled in according to the policy of the `BorderImage` subclass.

The standard subclasses of `BorderExtender` are `BorderExtenderZero`, which fills pixels with zeros; `BorderExtenderConstant`, which fills pixels with a given constant value; `BorderExtenderCopy`, which copies the edge pixels of the image; `BorderExtenderWrap`, which tiles the plane with repeating copies of the image; and `BorderExtenderReflect`, which is like `BorderExtenderWrap` except that each copy of the image is suitably reflected. Instances of `BorderExtenderConstant` are constructed in the usual way. Instances of the other standard subclasses are obtained by means of the `createInstance()` method of this class.

`BorderExtenderCopy` is particularly useful as a way of padding image data prior to performing area or geometric operations such as convolution, scaling, and rotation.

The standard subclasses of `BorderExtender` are marked as `final` in order to allow for optimizations in their use. It is possible to write new subclasses that implement different extension policies.

### See Also:

`PlanarImage.getExtendedData(java.awt.Rectangle, javax.media.jai.BorderExtender)`,  
`PlanarImage.copyExtendedData(java.awt.image.WritableRaster, javax.media.jai.BorderExtender)`, `BorderExtenderZero`, `BorderExtenderConstant`,  
`BorderExtenderCopy`, `BorderExtenderReflect`, `BorderExtenderWrap`

---

## Field Detail

### BORDER\_ZERO

public static final int **BORDER\_ZERO**  
A constant for use in the `createInstance` method.

---

### BORDER\_COPY

public static final int **BORDER\_COPY**  
A constant for use in the `createInstance` method.

---

### BORDER\_REFLECT

public static final int **BORDER\_REFLECT**  
A constant for use in the `createInstance` method.

---

### BORDER\_WRAP

public static final int **BORDER\_WRAP**  
A constant for use in the `createInstance` method.

---

## borderExtenderZero

```
private static final BorderExtender borderExtenderZero
```

---

## borderExtenderCopy

```
private static final BorderExtender borderExtenderCopy
```

---

## borderExtenderReflect

```
private static final BorderExtender borderExtenderReflect
```

---

## borderExtenderWrap

```
private static final BorderExtender borderExtenderWrap
```

### Constructor Detail

## BorderExtender

```
public BorderExtender()
```

### Method Detail

## extend

```
public abstract void extend(java.awt.image.WritableRaster raster,  
                             PlanarImage im)
```

Fills in the portions of a given Raster that lie outside the bounds of a given PlanarImage with data derived from that PlanarImage.

The portion of raster that lies within `im.getBounds()` must not be altered. The pixels within this region should not be assumed to have any particular values.

Each subclass may implement a different policy regarding how the extension data is computed.

---

## createInstance

```
public static BorderExtender createInstance(int extenderType)
```

Returns an instance of BorderExtender that implements a given extension policy. The policies understood by this method are:

BORDER\_ZERO: set sample values to zero.

BORDER\_COPY: set sample values to copies of the nearest valid pixel. For example, pixels to the left of the valid rectangle will take on the value of the valid edge pixel in the same row. Pixels both above and to the left of the valid rectangle will take on the value of the upper-left pixel.

BORDER\_REFLECT: the output image is defined as if mirrors were placed along the edges of the source image. Thus if the left edge of the valid rectangle lies at  $X = 10$ , pixel (9, Y) will be a copy of pixel (10, Y); pixel (6, Y) will be a copy of pixel (13, Y).

BORDER\_WRAP: the source image is tiled repeatedly in the plane.

Note that this method may not be used to create an instance of BorderExtenderConstant.

Any other input value will cause an IllegalArgumentException to be thrown.

**javax.media.jai**

## Class BorderExtenderConstant

```
java.lang.Object
```

```
+--javax.media.jai.BorderExtender
```

```

+--javax.media.jai.BorderExtenderConstant

```

public final class **BorderExtenderConstant**

extends `BorderExtender`

A subclass of `BorderExtender` that implements border extension by filling all pixels outside of the image bounds with constant values. For example, the image:

A	B	C
D	E	F
G	H	I

if extended by adding two extra rows to the top and bottom and two extra columns on the left and right sides, would become:

[illegible]

where X is the constant fill value. The set of constants is clamped to the range and precision of the data type of the Raster being filled. The number of constants used is given by the number of bands of the Raster. If the Raster has  $b$  bands, and there are  $c$  constants, constants 0 through  $b - 1$  are used when  $b \leq c$ . If  $b > c$ , zeros are used to fill out the constants array.

### See Also:

## BorderExtender

## Field Detail

**constants**

```
private double[] constants
```

## Constructor Detail

## BorderExtenderConstant

```
public BorderExtenderConstant(double[] constants)
```

Constructs an instance of `BorderExtenderConstant` with a given set of constants. The constants are specified as an array of doubles.

## Method Detail

## clamp

```
private int clamp(int band,
                  int min,
                  int max)
```

**extend**

```
public final void extend(java.awt.image.WritableRaster raster,
                        PlanarImage im)
```

Fills in the portions of a given `Raster` that lie outside the bounds of a given `PlanarImage` with constant values.

The portion of raster that lies within `im.getBounds()` is not altered.

### Overrides:

```

    extend in class BorderExtender

```

---

## javax.media.jai Class BorderExtenderCopy

```
java.lang.Object
|
+-- javax.media.jai.BorderExtender
|   |
|   +-- javax.media.jai.BorderExtenderCopy
```

---

public class **BorderExtenderCopy**  
extends BorderExtender

A subclass of BorderExtender that implements border extension by filling all pixels outside of the image bounds with copies of the edge pixels. For example, the image:

A	B	C
D	E	F
G	H	I

if extended by adding two extra rows to the top and bottom and two extra columns on the left and right sides, would become:

A	A	A	B	C	C	C	A	A	A	B	C	C	C	A	A	A	B	C	C	C	D	D	D	E	F	F	F	G	G	G	H	I	I	I	G	G	G	H	I	I	I	G	G	G	H	I	I	I
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

Although this type of extension is not particularly visually appealing, it is very useful as a way of padding source images prior to area or geometric operations, such as convolution, scaling, or rotation.

### See Also:

**BorderExtenderCopy**()

## Method Detail

### extend

```
public final void extend(java.awt.image.WritableRaster raster,  
                          PlanarImage im)
```

Fills in the portions of a given Raster that lie outside the bounds of a given PlanarImage with copies of the edge pixels of the image.

The portion of raster that lies within `im.getBounds()` is not altered.

#### Overrides:

extend in class BorderExtender

---

## javax.media.jai Class BorderExtenderReflect

```
java.lang.Object
|
+-- javax.media.jai.BorderExtender
|
+-- javax.media.jai.BorderExtenderReflect
```

---

public class **BorderExtenderReflect**  
extends BorderExtender

A subclass of BorderExtender that implements border extension by filling all pixels outside of the image bounds with copies of the whole image. For example, the image:

if extended by adding two extra rows to the top and bottom and one extra column on the left and right sides, would become:

This form of extension avoids discontinuities around the edges of the image.

---

### Constructor Detail

#### BorderExtenderReflect

**BorderExtenderReflect**()

### Method Detail

#### flipX

private void **flipX**(java.awt.image.WritableRaster raster)

#### flipY

private void **flipY**(java.awt.image.WritableRaster raster)

#### extend

public final void **extend**(java.awt.image.WritableRaster raster,  
PlanarImage im)

Fills in the portions of a given Raster that lie outside the bounds of a given PlanarImage with suitably reflected copies of the entire image.

The portion of raster that lies within im.getBounds() is not altered.

**Overrides:**

extend in class BorderExtender

---

## javax.media.jai Class BorderExtenderWrap

```
java.lang.Object
|
+-- javax.media.jai.BorderExtender
|
+-- javax.media.jai.BorderExtenderWrap
```

---

public class **BorderExtenderWrap**  
extends BorderExtender

A subclass of BorderExtender that implements border extension by filling all pixels outside of the image bounds with copies of the whole image. For example, the image:

A	B	C
D	E	F
G	H	I

if extended by adding two extra rows to the top and bottom and two extra columns on the left and right sides, would become:

E	F	D	E	F	D	E	H	I	G	H	I	G	H	B	C	A	B	C	A	B	E	F	D	E	F	D	E	H	I	G	H	I	G	H	B	C	A	B	C	A	B	E	F	D	E	F	D	E
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

This form of extension is appropriate for data that is inherently periodic, such as the Fourier transform of an image, or a wallpaper pattern.

**See Also:**

### Method Detail

#### extend

```
public final void extend(java.awt.image.WritableRaster raster,  
                        PlanarImage im)
```

Fills in the portions of a given Raster that lie outside the bounds of a given PlanarImage with copies of the entire image.

The portion of raster that lies within `im.getBounds()` is not altered.

**Overrides:**

extend in class BorderExtender

```
java.lang.Object
|
+--javax.media.jai.BorderExtender
|
+--javax.media.jai.BorderExtenderZero
```

A subclass of `BorderExtender` that implements border extension by filling all pixels outside of the image bounds with zeros. For example, the image:

A	B	C
D	E	F
G	H	I

[illegible]

## BorderExtender

## BorderExtenderZero

## Method Detail

Fills in the portions of a given `Raster` that lie outside the bounds of a given `PlanarImage` with zeros. The portion of `raster` that lies within `im.getBounds()` is not altered.

```

extend in class BorderExtender

```

---

## javax.media.jai Class CanvasJAI

```
java.lang.Object
|
+-- java.awt.Component
|   |
|   +-- java.awt.Canvas
|       |
|       +-- javax.media.jai.CanvasJAI
```

---

public class **CanvasJAI**  
extends java.awt.Canvas

An extension of java.awt.Canvas for use with JAI. CanvasJAI automatically returns an instance of GraphicsJAI from its getGraphics() method. This guarantees that the update(Graphics g) and paint(Graphics g) methods will receive a GraphicsJAI instance for accelerated rendering of JAI images.

In circumstances where it is not possible to use CanvasJAI, a similar effect may be obtained by manually calling GraphicsJAI.createGraphicsJAI() to "wrap" a Graphics2D object.

### See Also:

GraphicsJAI

---

## Constructor Detail

### CanvasJAI

public **CanvasJAI**(java.awt.GraphicsConfiguration config)

Constructs an instance of CanvasJAI using the given GraphicsConfiguration.

## Method Detail

### getGraphics

public java.awt.Graphics **getGraphics**()

Returns an instance of GraphicsJAI for drawing to this canvas.

#### Overrides:

getGraphics in class java.awt.Component

---

## javax.media.jai Class CollectionImage

java.lang.Object

└-- javax.media.jai.CollectionImage

### Direct Known Subclasses:

CollectionOp, ImageSequence, ImageStack

---

public abstract class **CollectionImage**  
extends java.lang.Object  
implements ImageJAI, java.util.Collection

An abstract superclass for classes representing a collection of images. It may be a collection of rendered or renderable images, a collection of collections that include images. In other words, this class supports nested collections, but at the very bottom, there must be images associated with the collection objects.

---

## Field Detail

### imageCollection

protected java.util.Collection **imageCollection**

A collection of objects. It may be a collection of images of the same type, a collection of objects of the same type, each contains an image, or a collection of collections whose leaf objects are images or objects that contain images.

---

## Constructor Detail

### CollectionImage

protected **CollectionImage**()

Default constructor. The `imageCollection` parameter is `null`. Subclasses that use this constructor must either set the `imageCollection` parameter themselves, or override the methods defined in `Collection` interface. Otherwise, `NullPointerException` may be thrown.

---

### CollectionImage

public **CollectionImage**(java.util.Collection collection)

Constructs a class that contains an image collection.

#### Parameters:

collection - A collection of objects that include images.

#### Throws:

NullPointerException - if collection is null.

---

## Method Detail

### getPropertyNames

public java.lang.String[] **getPropertyNames**()

Returns an array of `Strings` recognized as names by this property source. If no property names match, `null` will be returned. The default implementation returns `null`, i.e., no property names are recognized.

#### Returns:

An array of `Strings` giving the valid property names.

---

### getPropertyNames

public java.lang.String[] **getPropertyNames**(java.lang.String prefix)

Returns an array of `Strings` recognized as names by this property source that begin with the supplied prefix. If no property names are recognized, or no property names match, `null` will be returned. The comparison is done in a case-independent manner.

The default implementation calls `getPropertyNames` and searches the list of names for matches.

---

**Returns:**

An array of Strings giving the valid property names.

**Throws:**

NullPointerException - if prefix is null.

---

**getProperty**

```
public java.lang.Object getProperty(java.lang.String name)
```

Returns the specified property. The default implementation returns `java.awt.Image.UndefinedProperty`.

---

**getProperty**

```
public java.lang.Object getProperty(java.lang.String name,  
                                     java.util.Collection collection)
```

Returns the specified property. The default implementation returns `java.awt.Image.UndefinedProperty`.

---

**size**

```
public int size()
```

Returns the number of elements in this collection.

**Specified by:**

size in interface `java.util.Collection`

---

**isEmpty**

```
public boolean isEmpty()
```

Returns true if this collection contains no elements.

**Specified by:**

isEmpty in interface `java.util.Collection`

---

**contains**

```
public boolean contains(java.lang.Object o)
```

Returns true if this collection contains the specified object.

**Specified by:**

contains in interface `java.util.Collection`

---

**iterator**

```
public java.util.Iterator iterator()
```

Returns an Iterator over the elements in this collection.

**Specified by:**

iterator in interface `java.util.Collection`

---

**toArray**

```
public java.lang.Object[] toArray()
```

Returns an array containing all of the elements in this collection.

**Specified by:**

toArray in interface `java.util.Collection`

---

**toArray**

```
public java.lang.Object[] toArray(java.lang.Object[] a)
```

Returns an array containing all of the elements in this collection whose runtime type is that of the specified array.

**Specified by:**

toArray in interface `java.util.Collection`

**Throws:**

ArrayStoreException - if the runtime type of the specified array is not a supertype of the runtime type of every element in this collection.

---

## add

```
public boolean add(java.lang.Object o)
```

Adds the specified object to this collection.

**Specified by:**  
add in interface java.util.Collection

**Returns:**  
true if and only if the parameter is added to the collection.

---

## remove

```
public boolean remove(java.lang.Object o)
```

Removes the specified object from this collection.

**Specified by:**  
remove in interface java.util.Collection

**Returns:**  
true if and only if the parameter is removed from the collection.

---

## containsAll

```
public boolean containsAll(java.util.Collection c)
```

Returns true if this collection contains all of the elements in the specified collection.

**Specified by:**  
containsAll in interface java.util.Collection

---

## addAll

```
public boolean addAll(java.util.Collection c)
```

Adds all of the elements in the specified collection to this collection.

**Specified by:**  
addAll in interface java.util.Collection

**Returns:**  
true if this collection changed as a result of the call.

---

## removeAll

```
public boolean removeAll(java.util.Collection c)
```

Removes all this collection's elements that are also contained in the specified collection.

**Specified by:**  
removeAll in interface java.util.Collection

**Returns:**  
true if this collection changed as a result of the call.

---

## retainAll

```
public boolean retainAll(java.util.Collection c)
```

Retains only the elements in this collection that are contained in the specified collection.

**Specified by:**  
retainAll in interface java.util.Collection

**Returns:**  
true if this collection changed as a result of the call.

---

## clear

```
public void clear()
```

Removes all of the elements from this collection.

**Specified by:**  
clear in interface java.util.Collection

---

---

**javax.media.jai**  
**Interface CollectionImageFactory**

---

public abstract interface **CollectionImageFactory**

The `CollectionImageFactory` interface (often abbreviated CIF) is intended to be implemented by classes that wish to act as factories to produce different collection image operators.

---

<b>Method Detail</b>
----------------------

**create**

```
public CollectionImage create(java.awt.image.renderable.ParameterBlock args,  
                               java.awt.RenderingHints hints)
```

Creates a `CollectionImage` that represents the result of an operation (or chain of operations) for a given `ParameterBlock` and `RenderingHints`. If the operation is unable to handle the input arguments, this method should return null.

**Parameters:**

args - Input arguments to the operation, including sources and/or parameters.  
hints - The rendering hints.

**Returns:**

A `CollectionImage` containing the desired output.

---

## javax.media.jai Class CollectionOp

```
java.lang.Object
|
+-- javax.media.jai.CollectionImage
|
+-- javax.media.jai.CollectionOp
```

---

public class **CollectionOp**  
extends CollectionImage

A node in either a rendered or a renderable image chain representing a CollectionImage.

This class stores an OperationRegistry that is used to render this node, the name of the operation in the form of a String, a ParameterBlock that contains the input sources and parameters to the operation, and a RenderingHints that contains the hints used with the rendering.

The OperationRegistry may be specified at the construction time of this class, or later using the setRegistry method. If the registry is not specified, the default registry is used to render this node.

When any of the Collection methods is called on this class, this node is implicitly rendered and frozen. The result returned is the result of the rendered image collection. The getCollection method also causes this node to be rendered and frozen.

This node may be rendered explicitly by means of the createInstance() method. This method returns a Collection rendering without freezing the node. This allows a chain to be manipulated dynamically and rendered multiple times.

### See Also:

CollectionImage, RenderableOp, RenderedOp

---

## Field Detail

### registry

private OperationRegistry **registry**

The OperationRegistry that is used to render this node.

---

### opName

private java.lang.String **opName**

The name of the operation this node represents.

---

### args

private java.awt.image.renderable.ParameterBlock **args**

The input arguments for this operation, including sources and/or parameters.

---

### hints

private java.awt.RenderingHints **hints**

The rendering hints to use for this operation.

---

## Constructor Detail

### CollectionOp

```
public CollectionOp(OperationRegistry registry,  
                    java.lang.String opName,  
                    java.awt.image.renderable.ParameterBlock args,  
                    java.awt.RenderingHints hints)
```

Constructs a CollectionOp that will be used to instantiate a particular collection operation from a given operation registry, an operation name, a ParameterBlock, and a set of rendering hints. All input parameters are saved by reference.

#### Parameters:

registry - The OperationRegistry to be used for instantiation. if null, the default registry is used.

opName - The operation name.

args - The sources and other parameters. If null, it is assumed that this node has no sources and parameters.

hints - The rendering hints. If null, it is assumed that no hints are associated with the rendering.

**Throws:**  
NullPointerException - if opName is null.

---

## CollectionOp

```
public CollectionOp(java.lang.String opName,  
                   java.awt.image.renderable.ParameterBlock args,  
                   java.awt.RenderingHints hints)
```

Constructs a CollectionOp that will be used to instantiate a particular collection operation from a given operation name, a ParameterBlock, and a set of rendering hints. The default operation registry is used. All input parameters are saved by reference.

**Parameters:**

opName - The operation name.  
args - The sources and other parameters. If null, it is assumed that this node has no sources and parameters.  
hints - The rendering hints. If null, it is assumed that no hints are associated with the rendering.

**Throws:**  
NullPointerException - if opName is null.

---

## CollectionOp

```
public CollectionOp(OperationRegistry registry,  
                   java.lang.String opName,  
                   java.awt.image.renderable.ParameterBlock args)
```

Constructs a CollectionOp that will be used to instantiate a particular collection operation from a given operation registry, an operation name, and a ParameterBlock. There are no rendering hints associated with this operation. All input parameters are saved by reference.

**Parameters:**

registry - The OperationRegistry to be used for instantiation. If null, the default registry is used.  
opName - The operation name.  
args - The sources and other parameters. If null, it is assumed that this node has no sources and parameters.

**Throws:**  
NullPointerException - if opName is null.

---

## Method Detail

### getRegistry

```
public OperationRegistry getRegistry()
```

Returns the OperationRegistry that is used by this node. If the registry had not been set, the default registry is returned.

---

### setRegistry

```
public void setRegistry(OperationRegistry registry)
```

Sets the OperationRegistry that is used by this node. If the specified registry is null, the default registry is used. If this node has been rendered and frozen, this method has no effect. The parameter is saved by reference.

**Parameters:**

registry - The new OperationRegistry to be set; it may be null.

---

### getOperationName

```
public java.lang.String getOperationName()
```

Returns the name of the operation this node represents as a String.

---

### setOperationName

```
public void setOperationName(java.lang.String opName)
```

Sets the name of the operation this node represents. If this node has been rendered and frozen, this method has no effect. The parameter is saved by reference.

**Parameters:**

opName - The new operation name to be set.

**Throws:**  
NullPointerException - if opName is null.

---

## getParameterBlock

public java.awt.image.renderable.ParameterBlock **getParameterBlock()**

Returns the ParameterBlock of this node.

---

## setParameterBlock

public void **setParameterBlock**(java.awt.image.renderable.ParameterBlock pb)

Sets the ParameterBlock of this node. If this node has been rendered and frozen, this method has no effect. If the specified new ParameterBlock is null, it is assumed that this node has no input sources and parameters. The parameter is saved by reference.

This method does not validate the content of the supplied ParameterBlock. The caller should ensure that the sources and parameters in the ParameterBlock are suitable for the operation this node represents; otherwise some form of error or exception may occur at the time of rendering.

**Parameters:**

pb - The new ParameterBlock to be set; it may be null.

---

## getRenderingHints

public java.awt.RenderingHints **getRenderingHints()**

Returns the RenderingHints of this node. It may be null.

---

## setRenderingHints

public void **setRenderingHints**(java.awt.RenderingHints hints)

Sets the RenderingHints of this node. If this node has been rendered and frozen, this method has no effect. The parameter is saved by reference.

**Parameters:**

hints - The new RenderingHints to be set; it may be null.

---

## getCollection

public java.util.Collection **getCollection()**

Returns the collection rendering associated with this operation.

---

## createCollection

private void **createCollection()**

Creates a collection rendering if none exists.

---

## createInstance

public java.util.Collection **createInstance()**

Instantiates a collection operator that computes the result of this CollectionOp.

This method does not validate the sources and parameters stored in the ParameterBlock against the specification of the operation this node represents. It is the responsibility of the caller to ensure that the data in the ParameterBlock are suitable for this operation. Otherwise, some kind of exception or error will occur.

---

## createInstance

private java.util.Collection **createInstance**(boolean isChainFrozen)

This method performs the actions described by the documentation of createInstance() optionally freezing the image chain as a function of the parameter.

---

## size

```
public int size()
```

Returns the number of elements in this collection.

**Overrides:**  
size in class CollectionImage

---

## isEmpty

```
public boolean isEmpty()
```

Returns true if this collection contains no element.

**Overrides:**  
isEmpty in class CollectionImage

---

## contains

```
public boolean contains(java.lang.Object o)
```

Returns true if this collection contains the specified object.

**Overrides:**  
contains in class CollectionImage

---

## iterator

```
public java.util.Iterator iterator()
```

Returns an iterator over the elements in this collection.

**Overrides:**  
iterator in class CollectionImage

---

## toArray

```
public java.lang.Object[] toArray()
```

Returns an array containing all of the elements in this collection.

**Overrides:**  
toArray in class CollectionImage

---

## toArray

```
public java.lang.Object[] toArray(java.lang.Object[] a)
```

Returns an array containing all of the elements in this collection whose runtime type is that of the specified array.

**Throws:**  
ArrayStoreException - if the runtime type of the specified array is not a supertype of the runtime type of every element in this collection.

**Overrides:**  
toArray in class CollectionImage

---

## add

```
public boolean add(java.lang.Object o)
```

Adds the specified object to this collection.

**Overrides:**  
add in class CollectionImage

---

## remove

```
public boolean remove(java.lang.Object o)
```

Removes the specified object from this collection.

**Overrides:**  
remove in class CollectionImage

---

### **containsAll**

public boolean **containsAll**(java.util.Collection c)

Returns true if this collection contains all of the elements in the specified collection.

**Overrides:**

containsAll in class CollectionImage

---

### **addAll**

public boolean **addAll**(java.util.Collection c)

Adds all of the elements in the specified collection to this collection.

**Overrides:**

addAll in class CollectionImage

---

### **removeAll**

public boolean **removeAll**(java.util.Collection c)

Removes all this collection's elements that are also contained in the specified collection.

**Overrides:**

removeAll in class CollectionImage

---

### **retainAll**

public boolean **retainAll**(java.util.Collection c)

Retains only the elements in this collection that are contained in the specified collection.

**Overrides:**

retainAll in class CollectionImage

---

### **clear**

public void **clear**()

Removes all of the elements from this collection.

**Overrides:**

clear in class CollectionImage

---

## javax.media.jai Class ColorCube

```
java.lang.Object
|
+-- javax.media.jai.LookupTableJAI
|
+-- javax.media.jai.ColorCube
```

---

public class **ColorCube**  
extends LookupTableJAI

A subclass of LookupTableJAI which represents a lookup table which is a color cube. A color cube provides a fixed, invertible mapping between table indices and sample values. This allows the findNearestEntry method to be implemented more efficiently than in the general case.

All constructors are protected. The correct way to create a ColorCube is to use one of the static create methods defined in this class.

### See Also:

LookupTableJAI

---

## Field Detail

### BYTE\_496

public static final ColorCube **BYTE\_496**

A ColorCube for dithering RGB byte data into 216 colors. The offset of this ColorCube is 38.

---

### BYTE\_855

public static final ColorCube **BYTE\_855**

A ColorCube for dithering YCC byte data into 200 colors. The offset of this ColorCube is 54.

---

### dimension

private int[] **dimension**

The signed array of sizes used to create the ColorCube.

---

### dimsLessOne

private int[] **dimsLessOne**

An array of positive values each of whose elements is one less than the absolute value of the corresponding element of the dimension array.

---

### multipliers

private int[] **multipliers**

An array of multipliers.

The magnitudes of the elements of the multiplier array are defined as `multipliers[0] = 1` and `multipliers[i] = multipliers[i-1]*Math.abs(dimension[i-1])` where `i > 0`. The elements are subsequently assigned the same sign (positive or negative) as the corresponding elements of the dimension array.

---

### adjustedOffset

private int **adjustedOffset**

An offset into the lookup table, accounting for negative dimensions.

---

## dataType

private int **dataType**

The data type cached to accelerate findNearestEntry().

---

## numBands

private int **numBands**

The number of bands cached to accelerate findNearestEntry().

---

## Constructor Detail

### ColorCube

protected **ColorCube**(byte[][] data,  
                        int offset)

Returns a multi-banded byte ColorCube with an index offset common to all bands.

**Parameters:**

data - The multi-banded byte data in [band][index] format.  
offset - The common offset for all bands.

**Throws:**

NullPointerException - if data is null.

---

### ColorCube

protected **ColorCube**(short[][] data,  
                        int offset,  
                        boolean isUShort)

Returns a multi-banded short or unsigned short ColorCube with an index offset common to all bands.

**Parameters:**

data - The multi-banded short data in [band][index] format.  
offset - The common offset for all bands.  
isUShort - True if data type is DataBuffer.TYPE\_USHORT; false if data type is DataBuffer.TYPE\_SHORT.

**Throws:**

NullPointerException - if data is null.

---

### ColorCube

protected **ColorCube**(int[][] data,  
                        int offset)

Returns a multi-banded int ColorCube with an index offset common to all bands.

**Parameters:**

data - The multi-banded int data in [band][index] format.  
offset - The common offset for all bands.

**Throws:**

NullPointerException - if data is null.

---

### ColorCube

protected **ColorCube**(float[][] data,  
                        int offset)

Returns a multi-banded float ColorCube with an index offset common to all bands.

**Parameters:**

data - The multi-banded float data in [band][index] format.  
offset - The common offset for all bands.

**Throws:**

NullPointerException - if data is null.

---

## ColorCube

```
protected ColorCube(double[][] data,  
                    int offset)
```

Returns a multi-banded double ColorCube with an index offset common to all bands.

**Parameters:**

data - The multi-banded double data in [band][index] format.  
offset - The common offset for all bands.

**Throws:**

NullPointerException - if data is null.

## Method Detail

### createColorCube

```
public static ColorCube createColorCube(int dataType,  
                                       int offset,  
                                       int[] dimension)
```

Returns a multi-banded ColorCube of a specified data type.

**Parameters:**

dataType - the data type of the ColorCube, one of DataBuffer.TYPE\_BYTE, TYPE\_SHORT, TYPE\_USHORT, TYPE\_INT, TYPE\_FLOAT, or TYPE\_DOUBLE.  
offset - The common offset for all bands.  
dimension - The signed dimension of each band.

**Returns:**

An appropriate ColorCube.

**Throws:**

NullPointerException - if dimension is null.

### createColorCube

```
public static ColorCube createColorCube(int dataType,  
                                       int[] dimension)
```

Returns a multi-banded ColorCube of a specified data type with zero offset for all bands.

**Parameters:**

dataType - The data type of the ColorCube.  
dimension - The signed dimension of each band.

**Returns:**

An appropriate ColorCube.

**Throws:**

NullPointerException - if dimension is null.

### createColorCubeByte

```
private static ColorCube createColorCubeByte(int offset,  
                                             int[] dimension)
```

Returns a multi-banded byte ColorCube with an index offset common to all bands.

**Parameters:**

offset - The common offset for all bands.  
dimension - An array of signed sizes of each side of the color cube. The color ramp in each dimension will be increasing or decreasing according to whether the sign of the corresponding element of the dimension array is positive or negative, respectively.

**Returns:**

A multi-banded byte ColorCube with offset.

### createColorCubeShort

```
private static ColorCube createColorCubeShort(int offset,  
                                             int[] dimension)
```

Returns a multi-banded short ColorCube with an index offset common to all bands.

**Parameters:**

offset - The common offset for all bands.  
dimension - An array of signed sizes of each side of the color cube. The color ramp in each dimension will be increasing or decreasing according to whether the sign of the corresponding element of the dimension array is positive or negative, respectively.

**Returns:**

A multi-banded short `ColorCube` with offset.

---

**createColorCubeUShort**

```
private static ColorCube createColorCubeUShort(int offset,
                                              int[] dimension)
```

Returns a multi-banded unsigned short `ColorCube` with an index offset common to all bands.

**Parameters:**

`offset` - The common offset for all bands.

`dimension` - An array of signed sizes of each side of the color cube. The color ramp in each dimension will be increasing or decreasing according to whether the sign of the corresponding element of the dimension array is positive or negative, respectively.

**Returns:**

A multi-banded unsigned short `ColorCube` with offset.

---

**createColorCubeInt**

```
private static ColorCube createColorCubeInt(int offset,
                                           int[] dimension)
```

Returns a multi-banded int `ColorCube` with an index offset common to all bands.

**Parameters:**

`offset` - The common offset for all bands.

`dimension` - An array of signed sizes of each side of the color cube. The color ramp in each dimension will be increasing or decreasing according to whether the sign of the corresponding element of the dimension array is positive or negative, respectively.

**Returns:**

A multi-banded int `ColorCube` with offset.

---

**createColorCubeFloat**

```
private static ColorCube createColorCubeFloat(int offset,
                                              int[] dimension)
```

Returns a multi-banded float `ColorCube` with an index offset common to all bands.

**Parameters:**

`offset` - The common offset for all bands.

`dimension` - An array of signed sizes of each side of the color cube. The color ramp in each dimension will be increasing or decreasing according to whether the sign of the corresponding element of the dimension array is positive or negative, respectively.

**Returns:**

A multi-banded float `ColorCube` with offset.

---

**createColorCubeDouble**

```
private static ColorCube createColorCubeDouble(int offset,
                                              int[] dimension)
```

Returns a multi-banded double `ColorCube` with an index offset common to all bands.

**Parameters:**

`offset` - The common offset for all bands.

`dimension` - An array of signed sizes of each side of the color cube. The color ramp in each dimension will be increasing or decreasing according to whether the sign of the corresponding element of the dimension array is positive or negative, respectively.

**Returns:**

A multi-banded double `ColorCube`.

---

**createDataArray**

```
private static java.lang.Object createDataArray(int dataType,
                                              int offset,
                                              int[] dimension)
```

Constructs a two-dimensional array of the requested data type which represents the contents of a color cube.

**Parameters:**

`dataType` - The data type as defined by the static `TYPE` fields of `DataBuffer`, e.g., `DataBuffer.TYPE_BYTE`.

`offset` - The initial offset into the data array.

`dimension` - An array of signed sizes of each side of the color cube. The color ramp in each dimension will be

increasing or decreasing according to whether the sign of the corresponding element of the dimension array is positive or negative, respectively.

**Returns:**

A two-dimensional array of the requested data type laid out in color cube format.

**See Also:**

`DataBuffer`

---

## **createDataArrayByte**

```
private static byte[][] createDataArrayByte(int offset,  
                                             int[] dimension)
```

Constructs a two-dimensional array of byte data which represent the contents of a color cube.

**Parameters:**

`offset` - The initial offset into the data array.

`dimension` - An array of signed sizes of each side of the color cube. The color ramp in each dimension will be increasing or decreasing according to whether the sign of the corresponding element of the dimension array is positive or negative, respectively.

**Returns:**

A two-dimensional byte array of color cube data.

---

## **createDataArrayShort**

```
private static short[][] createDataArrayShort(int offset,  
                                              int[] dimension)
```

Constructs a two-dimensional array of short data which represent the contents of a color cube.

**Parameters:**

`offset` - The initial offset into the data array.

`dimension` - an array of signed sizes of each side of the color cube. The color ramp in each dimension will be increasing or decreasing according to whether the sign of the corresponding element of the dimension array is positive or negative, respectively.

**Returns:**

A two-dimensional short array of color cube data.

---

## **createDataArrayUShort**

```
private static short[][] createDataArrayUShort(int offset,  
                                              int[] dimension)
```

Constructs a two-dimensional array of unsigned short data which represent the contents of a color cube.

**Parameters:**

`offset` - The initial offset into the data array.

`dimension` - an array of signed sizes of each side of the color cube. The color ramp in each dimension will be increasing or decreasing according to whether the sign of the corresponding element of the dimension array is positive or negative, respectively.

**Returns:**

A two-dimensional short array of color cube data.

---

## **createDataArrayInt**

```
private static int[][] createDataArrayInt(int offset,  
                                           int[] dimension)
```

Constructs a two-dimensional array of int data which represent the contents of a color cube.

**Parameters:**

`offset` - The initial offset into the data array.

`dimension` - an array of signed sizes of each side of the color cube. The color ramp in each dimension will be increasing or decreasing according to whether the sign of the corresponding element of the dimension array is positive or negative, respectively.

**Returns:**

A two-dimensional int array of color cube data.

---

## createDataArrayFloat

```
private static float[][] createDataArrayFloat(int offset,  
                                              int[] dimension)
```

Constructs a two-dimensional array of float data which represent the contents of a color cube.

**Parameters:**

offset - The initial offset into the data array.

dimension - an array of signed sizes of each side of the color cube. The color ramp in each dimension will be increasing or decreasing according to whether the sign of the corresponding element of the dimension array is positive or negative, respectively.

**Returns:**

A two-dimensional float array of color cube data.

---

## createDataArrayDouble

```
private static double[][] createDataArrayDouble(int offset,  
                                              int[] dimension)
```

Constructs a two-dimensional array of double data which represent the contents of a color cube.

**Parameters:**

offset - The initial offset into the data array.

dimension - an array of signed sizes of each side of the color cube. The color ramp in each dimension will be increasing or decreasing according to whether the sign of the corresponding element of the dimension array is positive or negative, respectively.

**Returns:**

A two-dimensional double array of color cube data.

---

## initFields

```
private void initFields(int offset,  
                      int[] dimension)
```

Initialize the fields of a ColorCube.

**Parameters:**

offset - The common offset for all bands.

dimension - The signed dimension for each band.

---

## getDimension

```
public int[] getDimension()
```

Returns the array of signed dimensions used to construct the ColorCube.

**Returns:**

the dimension array used to create the ColorCube.

---

## getDimsLessOne

```
public int[] getDimsLessOne()
```

Returns an array containing the signed dimensions, less one.

**Returns:**

An array of ints.

---

## getMultipliers

```
public int[] getMultipliers()
```

Get the multipliers as an array.

**Returns:**

the array of multipliers.

---

## getAdjustedOffset

```
public int getAdjustedOffset()
```

Get the adjusted offset into the lookup table, accounting for negative dimensions.

**Returns:**

The adjusted offset.

---

## **findNearestEntry**

`public int findNearestEntry(float[] pixel)`

Find the index of the nearest color in the color map to the pixel value argument.

**Parameters:**

pixel - a float array of all samples of a pixel.

**Returns:**

the index of the nearest color.

**Throws:**

NullPointerException - if pixel is null.

**Overrides:**

findNearestEntry in class LookupTableJAI

---

**javax.media.jai**

## **Class ComponentSampleModelJAI**

```
java.lang.Object
|
+-- java.awt.image.SampleModel
|   |
|   +-- java.awt.image.ComponentSampleModel
|       |
|       +-- javax.media.jai.ComponentSampleModelJAI
```

---

public class **ComponentSampleModelJAI**  
extends java.awt.image.ComponentSampleModel

This class represents image data which is stored such that each sample of a pixel occupies one data element of the DataBuffer. It stores the N samples which make up a pixel in N separate data array elements. Different bands may be in different banks of the DataBuffer. Accessor methods are provided so that image data can be manipulated directly. This class can support different kinds of interleaving, e.g. band interleaving, scanline interleaving, and pixel interleaving. Pixel stride is the number of data array elements between two samples for the same band on the same scanline. Scanline stride is the number of data array elements between a given sample and the corresponding sample in the same column of the next scanline. Band offsets denote the number of data array elements from the first data array element of the bank of the DataBuffer holding each band to the first sample of the band. The bands are numbered from 0 to N-1. This class can represent image data for the dataTypes enumerated in java.awt.image.DataBuffer (all samples of a given ComponentSampleModel are stored with the same precision) . All strides and offsets must be non-negative.

**See Also:**

ComponentSampleModel

---

### **Constructor Detail**

#### **ComponentSampleModelJAI**

```
public ComponentSampleModelJAI(int dataType,  
                                int w,  
                                int h,  
                                int pixelStride,  
                                int scanlineStride,  
                                int[] bandOffsets)
```

Constructs a ComponentSampleModel with the specified parameters. The number of bands will be given by the length of the bandOffsets array. All bands will be stored in the first bank of the DataBuffer.

**Parameters:**

dataType - The data type for storing samples.  
w - The width (in pixels) of the region of image data described.  
h - The height (in pixels) of the region of image data described.  
pixelStride - The pixel stride of the region of image data described.  
scanlineStride - The line stride of the region of image data described.  
bandOffsets - The offsets of all bands.

---

#### **ComponentSampleModelJAI**

```
public ComponentSampleModelJAI(int dataType,  
                                int w,  
                                int h,  
                                int pixelStride,  
                                int scanlineStride,  
                                int[] bankIndices,  
                                int[] bandOffsets)
```

Constructs a ComponentSampleModel with the specified parameters. The number of bands will be given by the length of the bandOffsets array. Different bands may be stored in different banks of the DataBuffer.

**Parameters:**

dataType - The data type for storing samples.  
w - The width (in pixels) of the region of image data described.  
h - The height (in pixels) of the region of image data described.  
pixelStride - The pixel stride of the region of image data described.  
scanlineStride - The line stride of the region of image data described.  
bankIndices - The bank indices of all bands.  
bandOffsets - The band offsets of all bands.

## Method Detail

### getBufferSize

```
private long getBufferSize()
```

Returns the size of the data buffer (in data elements) needed for a data buffer that matches this ComponentSampleModel.

**Overrides:**

getBufferSize in class java.awt.image.ComponentSampleModel

---

### JAIOrderBands

```
private int[] JAIOrderBands(int[] orig,
                             int step)
```

Preserves band ordering with new step factor...

---

### createCompatibleSampleModel

```
public java.awt.image.SampleModel createCompatibleSampleModel(int w,
                                                             int h)
```

Creates a new ComponentSampleModel with the specified width and height. The new SampleModel will have the same number of bands, storage data type, interleaving scheme, and pixel stride as this SampleModel.

**Parameters:**

w - The width in pixels.

h - The height in pixels

**Overrides:**

createCompatibleSampleModel in class java.awt.image.ComponentSampleModel

---

### createSubsetSampleModel

```
public java.awt.image.SampleModel createSubsetSampleModel(int[] bands)
```

This creates a new ComponentSampleModel with a subset of the bands of this ComponentSampleModel. The new ComponentSampleModel can be used with any DataBuffer that the existing ComponentSampleModel can be used with. The new ComponentSampleModel/DataBuffer combination will represent an image with a subset of the bands of the original ComponentSampleModel/DataBuffer combination.

**Parameters:**

bands - subset of bands of this ComponentSampleModel

**Overrides:**

createSubsetSampleModel in class java.awt.image.ComponentSampleModel

---

### createDataBuffer

```
public java.awt.image.DataBuffer createDataBuffer()
```

Creates a DataBuffer that corresponds to this ComponentSampleModel. The DataBuffer's data type, number of banks, and size will be consistent with this ComponentSampleModel.

**Overrides:**

createDataBuffer in class java.awt.image.ComponentSampleModel

---

### getDataElements

```
public java.lang.Object getDataElements(int x,
                                       int y,
                                       java.lang.Object obj,
                                       java.awt.image.DataBuffer data)
```

Returns data for a single pixel in a primitive array of type TransferType. For a ComponentSampleModel, this will be the same as the data type, and samples will be returned one per array element. Generally, obj should be passed in as null, so that the Object will be created automatically and will be of the right primitive data type.

The following code illustrates transferring data for one pixel from DataBuffer db1, whose storage layout is described by ComponentSampleModel csm1, to DataBuffer db2, whose storage layout is described by ComponentSampleModel csm2. The transfer will generally be more efficient than using getPixel/setPixel.

```
ComponentSampleModel csm1, csm2;
DataBufferInt db1, db2;
csm2.setDataElements(x, y,
                    csm1.getDataElements(x, y, null, db1), db2);
```

Using getDataElements/setDataElements to transfer between two DataBuffer/SampleModel pairs is legitimate if the

SampleModels have the same number of bands, corresponding bands have the same number of bits per sample, and the TransferTypes are the same.

If obj is non-null, it should be a primitive array of type TransferType. Otherwise, a ClassCastException is thrown. An ArrayIndexOutOfBoundsException may be thrown if the coordinates are not in bounds, or if obj is non-null and is not large enough to hold the pixel data.

**Parameters:**

- x - The X coordinate of the pixel location.
- y - The Y coordinate of the pixel location.
- obj - If non-null, a primitive array in which to return the pixel data.
- data - The DataBuffer containing the image data.

**Overrides:**

getDataElements in class java.awt.image.ComponentSampleModel

---

## getDataElements

```
public java.lang.Object getDataElements(int x,
                                         int y,
                                         int w,
                                         int h,
                                         java.lang.Object obj,
                                         java.awt.image.DataBuffer data)
```

Returns the pixel data for the specified rectangle of pixels in a primitive array of type TransferType. For image data supported by the Java 2D API, this will be one of the dataTypes supported by java.awt.image.DataBuffer. Data may be returned in a packed format, thus increasing efficiency for data transfers. Generally, obj should be passed in as null, so that the Object will be created automatically and will be of the right primitive data type.

The following code illustrates transferring data for a rectangular region of pixels from DataBuffer db1, whose storage layout is described by SampleModel sm1, to DataBuffer db2, whose storage layout is described by SampleModel sm2. The transfer will generally be more efficient than using getPixels/setPixels.

```
SampleModel sm1, sm2;
DataBuffer db1, db2;
sm2.setDataElements(x, y, w, h, sm1.getDataElements(x, y, w,
                                                    h, null, db1), db2);
```

Using getDataElements/setDataElements to transfer between two DataBuffer/SampleModel pairs is legitimate if the SampleModels have the same number of bands, corresponding bands have the same number of bits per sample, and the TransferTypes are the same.

If obj is non-null, it should be a primitive array of type TransferType. Otherwise, a ClassCastException is thrown. An ArrayIndexOutOfBoundsException may be thrown if the coordinates are not in bounds, or if obj is non-null and is not large enough to hold the pixel data.

**Parameters:**

- x - The minimum X coordinate of the pixel rectangle.
- y - The minimum Y coordinate of the pixel rectangle.
- w - The width of the pixel rectangle.
- h - The height of the pixel rectangle.
- obj - If non-null, a primitive array in which to return the pixel data.
- data - The DataBuffer containing the image data.

**Overrides:**

getDataElements in class java.awt.image.SampleModel

**See Also:**

ComponentSampleModel.getNumDataElements(), SampleModel.getTransferType(), DataBuffer

---

## setDataElements

```
public void setDataElements(int x,
                             int y,
                             java.lang.Object obj,
                             java.awt.image.DataBuffer data)
```

Sets the data for a single pixel in the specified DataBuffer from a primitive array of type TransferType. For a ComponentSampleModel, this will be the same as the data type, and samples are transferred one per array element.

The following code illustrates transferring data for one pixel from DataBuffer db1, whose storage layout is described by ComponentSampleModel csm1, to DataBuffer db2, whose storage layout is described by ComponentSampleModel csm2. The transfer will generally be more efficient than using getPixel/setPixel.

```
ComponentSampleModel csm1, csm2;
DataBufferInt db1, db2;
csm2.setDataElements(x, y, csm1.getDataElements(x, y, null, db1),
                    db2);
```

Using getDataElements/setDataElements to transfer between two DataBuffer/SampleModel pairs is legitimate if the

SampleModels have the same number of bands, corresponding bands have the same number of bits per sample, and the TransferTypes are the same.

obj must be a primitive array of type TransferType. Otherwise, a ClassCastException is thrown. An ArrayIndexOutOfBoundsException may be thrown if the coordinates are not in bounds, or if obj is not large enough to hold the pixel data.

**Parameters:**

- x - The X coordinate of the pixel location.
- y - The Y coordinate of the pixel location.
- obj - A primitive array containing pixel data.
- data - The DataBuffer containing the image data.

**Overrides:**

setDataElements in class java.awt.image.ComponentSampleModel

---

## setDataElements

```
public void setDataElements(int x,
                           int y,
                           int w,
                           int h,
                           java.lang.Object obj,
                           java.awt.image.DataBuffer data)
```

Sets the data for a rectangle of pixels in the specified DataBuffer from a primitive array of type TransferType. For image data supported by the Java 2D API, this will be one of the dataTypes supported by java.awt.image.DataBuffer. Data in the array may be in a packed format, thus increasing efficiency for data transfers.

The following code illustrates transferring data for a rectangular region of pixels from DataBuffer db1, whose storage layout is described by SampleModel sm1, to DataBuffer db2, whose storage layout is described by SampleModel sm2. The transfer will generally be more efficient than using getPixels/setPixels.

```
SampleModel sm1, sm2;
DataBuffer db1, db2;
sm2.setDataElements(x, y, w, h, sm1.getDataElements(x, y, w, h,
                                                    null, db1), db2);
```

Using getDataElements/setDataElements to transfer between two DataBuffer/SampleModel pairs is legitimate if the SampleModels have the same number of bands, corresponding bands have the same number of bits per sample, and the TransferTypes are the same.

obj must be a primitive array of type TransferType. Otherwise, a ClassCastException is thrown. An ArrayIndexOutOfBoundsException may be thrown if the coordinates are not in bounds, or if obj is not large enough to hold the pixel data.

**Parameters:**

- x - The minimum X coordinate of the pixel rectangle.
- y - The minimum Y coordinate of the pixel rectangle.
- w - The width of the pixel rectangle.
- h - The height of the pixel rectangle.
- obj - A primitive array containing pixel data.
- data - The DataBuffer containing the image data.

**Overrides:**

setDataElements in class java.awt.image.SampleModel

**See Also:**

ComponentSampleModel.getNumDataElements(), SampleModel.getTransferType(), DataBuffer

---

## setSample

```
public void setSample(int x,
                     int y,
                     int b,
                     float s,
                     java.awt.image.DataBuffer data)
```

Sets a sample in the specified band for the pixel located at (x,y) in the DataBuffer using a float for input. ArrayIndexOutOfBoundsException may be thrown if the coordinates are not in bounds.

**Parameters:**

- x - The X coordinate of the pixel location.
- y - The Y coordinate of the pixel location.
- b - The band to set.
- s - The input sample as a float.
- data - The DataBuffer containing the image data.

**Throws:**  
ArrayIndexOutOfBoundsException - if coordinates are not in bounds  
**Overrides:**  
setSample in class java.awt.image.SampleModel

---

## getSampleFloat

```
public float getSampleFloat(int x,  
                           int y,  
                           int b,  
                           java.awt.image.DataBuffer data)
```

Returns the sample in a specified band for the pixel located at (x,y) as a float. ArrayIndexOutOfBoundsException may be thrown if the coordinates are not in bounds.

**Parameters:**  
x - The X coordinate of the pixel location.  
y - The Y coordinate of the pixel location.  
b - The band to return.  
data - The DataBuffer containing the image data.

**Returns:**  
sample The floating point sample value

**Overrides:**  
getSampleFloat in class java.awt.image.SampleModel

---

## setSample

```
public void setSample(int x,  
                    int y,  
                    int b,  
                    double s,  
                    java.awt.image.DataBuffer data)
```

Sets a sample in the specified band for the pixel located at (x,y) in the DataBuffer using a double for input. ArrayIndexOutOfBoundsException may be thrown if the coordinates are not in bounds.

**Parameters:**  
x - The X coordinate of the pixel location.  
y - The Y coordinate of the pixel location.  
b - The band to set.  
s - The input sample as a double.  
data - The DataBuffer containing the image data.

**Throws:**  
ArrayIndexOutOfBoundsException - if coordinates are not in bounds

**Overrides:**  
setSample in class java.awt.image.SampleModel

---

## getSampleDouble

```
public double getSampleDouble(int x,  
                             int y,  
                             int b,  
                             java.awt.image.DataBuffer data)
```

Returns the sample in a specified band for a pixel located at (x,y) as a double. ArrayIndexOutOfBoundsException may be thrown if the coordinates are not in bounds.

**Parameters:**  
x - The X coordinate of the pixel location.  
y - The Y coordinate of the pixel location.  
b - The band to return.  
data - The DataBuffer containing the image data.

**Returns:**  
sample The double sample value

**Overrides:**  
getSampleDouble in class java.awt.image.SampleModel

---

## getPixels

```
public double[] getPixels(int x,  
                           int y,  
                           int w,  
                           int h,  
                           double[] dArray,  
                           java.awt.image.DataBuffer data)
```

Returns all samples for a rectangle of pixels in a double array, one sample per array element. `ArrayIndexOutOfBoundsException` may be thrown if the coordinates are not in bounds.

### Parameters:

x - The X coordinate of the upper left pixel location.  
y - The Y coordinate of the upper left pixel location.  
w - The width of the pixel rectangle.  
h - The height of the pixel rectangle.  
dArray - If non-null, returns the samples in this array.  
data - The `DataBuffer` containing the image data.

### Overrides:

`getPixels` in class `java.awt.image.SampleModel`

---

## toString

```
public java.lang.String toString()
```

Returns a `String` containing the values of all valid fields.

### Overrides:

`toString` in class `java.lang.Object`

---

## javax.media.jai Class CoordinateImage

java.lang.Object  
|  
+-- javax.media.jai.CoordinateImage

---

public class **CoordinateImage**  
extends java.lang.Object

A class representing an image that is associated with a coordinate. This class is used with ImageStack.

**See Also:**

ImageStack

---

### Field Detail

#### image

public PlanarImage **image**  
The image.

---

#### coordinate

public java.lang.Object **coordinate**

The coordinate associated with the image. The type of this parameter is Object so that the application may choose any class to represent a coordinate based on the individual's needs.

### Constructor Detail

#### CoordinateImage

public **CoordinateImage**(PlanarImage pi,  
                          java.lang.Object c)

Constructor.

**Throws:**

NullPointerException - if pi is null.  
NullPointerException - if c is null.

---

## javax.media.jai Class CopyPropertyGenerator

java.lang.Object  
|  
+-- javax.media.jai.CopyPropertyGenerator

---

class **CopyPropertyGenerator**  
extends java.lang.Object  
implements PropertyGenerator  
Copy properties from a PlanarImage rendering.

---

### Field Detail

#### im

PlanarImage im

### Constructor Detail

#### CopyPropertyGenerator

public **CopyPropertyGenerator**(PlanarImage im)

### Method Detail

#### getPropertyNames

public java.lang.String[] **getPropertyNames**()

**Specified by:**

getPropertyNames in interface PropertyGenerator

---

#### getProperty

public java.lang.Object **getProperty**(java.lang.String name,  
RenderedOp op)

**Specified by:**

getProperty in interface PropertyGenerator

---

#### getProperty

public java.lang.Object **getProperty**(java.lang.String name,  
RenderableOp op)

**Specified by:**

getProperty in interface PropertyGenerator

---

## javax.media.jai Class DataBufferDouble

```
java.lang.Object
|
+-- java.awt.image.DataBuffer
|   |
+-- javax.media.jai.DataBufferDouble
```

---

public class **DataBufferDouble**  
extends java.awt.image.DataBuffer  
An extension of DataBuffer that stores data internally in double form.  
**See Also:**  
DataBuffer

---

### Field Detail

**bankdata**  
protected double[][] **bankdata**  
The array of data banks.

---

**data**  
protected double[] **data**  
A reference to the default data bank.

---

### Constructor Detail

**DataBufferDouble**  
public **DataBufferDouble**(int size)  
Constructs a double-based DataBuffer with a specified size.  
**Parameters:**  
size - The number of elements in the DataBuffer.

---

**DataBufferDouble**  
public **DataBufferDouble**(int size,  
int numBanks)  
Constructs a double-based DataBuffer with a specified number of banks, all of which are of a specified size.  
**Parameters:**  
size - The number of elements in each bank of the DataBuffer.  
numBanks - The number of banks in the DataBuffer.

---

**DataBufferDouble**  
public **DataBufferDouble**(double[] dataArray,  
int size)  
Constructs a double-based DataBuffer with the specified data array. Only the first size elements are available for use by this DataBuffer. The array must be large enough to hold size elements.  
**Parameters:**  
dataArray - An array of doubles to be used as the first and only bank of this DataBuffer.  
size - The number of elements of the array to be used.

---

## DataBufferDouble

```
public DataBufferDouble(double[] dataArray,  
                        int size,  
                        int offset)
```

Constructs a double-based DataBuffer with the specified data array. Only the elements between offset and offset + size - 1 are available for use by this DataBuffer. The array must be large enough to hold offset + size elements.

**Parameters:**

dataArray - An array of doubles to be used as the first and only bank of this DataBuffer.

size - The number of elements of the array to be used.

offset - The offset of the first element of the array that will be used.

---

## DataBufferDouble

```
public DataBufferDouble(double[][] dataArray,  
                        int size)
```

Constructs a double-based DataBuffer with the specified data arrays. Only the first size elements of each array are available for use by this DataBuffer. The number of banks will be equal to dataArray.length.

**Parameters:**

dataArray - An array of arrays of doubles to be used as the banks of this DataBuffer.

size - The number of elements of each array to be used.

---

## DataBufferDouble

```
public DataBufferDouble(double[][] dataArray,  
                        int size,  
                        int[] offsets)
```

Constructs a double-based DataBuffer with the specified data arrays, size, and per-bank offsets. The number of banks is equal to dataArray.length. Each array must be at least as large as size plus the corresponding offset. There must be an entry in the offsets array for each data array.

**Parameters:**

dataArray - An array of arrays of doubles to be used as the banks of this DataBuffer.

size - The number of elements of each array to be used.

offsets - An array of integer offsets, one for each bank.

---

## Method Detail

### getData

```
public double[] getData()
```

Returns the default (first) double data array.

---

### getData

```
public double[] getData(int bank)
```

Returns the data array for the specified bank.

---

### getBankData

```
public double[][] getBankData()
```

Returns the data array for all banks.

---

### getElem

```
public int getElem(int i)
```

Returns the requested data array element from the first (default) bank as an int.

**Parameters:**

i - The desired data array element.

**Returns:**

The data entry as an int.

**Overrides:**  
getElem in class java.awt.image.DataBuffer

---

## getElem

```
public int getElem(int bank,  
                  int i)
```

Returns the requested data array element from the specified bank as an int.

**Parameters:**  
bank - The bank number.  
i - The desired data array element.

**Returns:**  
The data entry as an int.

**Overrides:**  
getElem in class java.awt.image.DataBuffer

---

## setElem

```
public void setElem(int i,  
                  int val)
```

Sets the requested data array element in the first (default) bank to the given int.

**Parameters:**  
i - The desired data array element.  
val - The value to be set.

**Overrides:**  
setElem in class java.awt.image.DataBuffer

---

## setElem

```
public void setElem(int bank,  
                  int i,  
                  int val)
```

Sets the requested data array element in the specified bank to the given int.

**Parameters:**  
bank - The bank number.  
i - The desired data array element.  
val - The value to be set.

**Overrides:**  
setElem in class java.awt.image.DataBuffer

---

## getElemFloat

```
public float getElemFloat(int i)
```

Returns the requested data array element from the first (default) bank as a float.

**Parameters:**  
i - The desired data array element.

**Returns:**  
The data entry as a float.

**Overrides:**  
getElemFloat in class java.awt.image.DataBuffer

---

## getElemFloat

```
public float getElemFloat(int bank,  
                          int i)
```

Returns the requested data array element from the specified bank as a float.

**Parameters:**  
bank - The bank number.  
i - The desired data array element.

**Returns:**  
The data entry as a float.

**Overrides:**  
getElemFloat in class java.awt.image.DataBuffer

---

### setElemFloat

```
public void setElemFloat(int i,  
                        float val)
```

Sets the requested data array element in the first (default) bank to the given float.

**Parameters:**

i - The desired data array element.  
val - The value to be set.

**Overrides:**

setElemFloat in class java.awt.image.DataBuffer

---

### setElemFloat

```
public void setElemFloat(int bank,  
                        int i,  
                        float val)
```

Sets the requested data array element in the specified bank to the given float.

**Parameters:**

bank - The bank number.  
i - The desired data array element.  
val - The value to be set.

**Overrides:**

setElemFloat in class java.awt.image.DataBuffer

---

### getElemDouble

```
public double getElemDouble(int i)
```

Returns the requested data array element from the first (default) bank as a double.

**Parameters:**

i - The desired data array element.

**Returns:**

The data entry as a double.

**Overrides:**

getElemDouble in class java.awt.image.DataBuffer

---

### getElemDouble

```
public double getElemDouble(int bank,  
                        int i)
```

Returns the requested data array element from the specified bank as a double.

**Parameters:**

bank - The bank number.  
i - The desired data array element.

**Returns:**

The data entry as a double.

**Overrides:**

getElemDouble in class java.awt.image.DataBuffer

---

### setElemDouble

```
public void setElemDouble(int i,  
                        double val)
```

Sets the requested data array element in the first (default) bank to the given double.

**Parameters:**

i - The desired data array element.  
val - The value to be set.

**Overrides:**

setElemDouble in class java.awt.image.DataBuffer

---

## **setElemDouble**

```
public void setElemDouble(int bank,  
                           int i,  
                           double val)
```

Sets the requested data array element in the specified bank to the given double.

### **Parameters:**

bank - The bank number.  
i - The desired data array element.  
val - The value to be set.

### **Overrides:**

setElemDouble in class java.awt.image.DataBuffer

---

## javax.media.jai Class DataBufferFloat

```
java.lang.Object
|
+-- java.awt.image.DataBuffer
|
+-- javax.media.jai.DataBufferFloat
```

---

public class **DataBufferFloat**  
extends java.awt.image.DataBuffer  
An extension of DataBuffer that stores data internally in float form.

**See Also:**  
DataBuffer

---

### Field Detail

#### bankdata

protected float[][] **bankdata**  
The array of data banks.

---

#### data

protected float[] **data**  
A reference to the default data bank.

---

### Constructor Detail

#### DataBufferFloat

public **DataBufferFloat**(int size)  
Constructs a float-based DataBuffer with a specified size.  
**Parameters:**  
size - The number of elements in the DataBuffer.

---

#### DataBufferFloat

public **DataBufferFloat**(int size,  
int numBanks)  
Constructs a float-based DataBuffer with a specified number of banks, all of which are of a specified size.  
**Parameters:**  
size - The number of elements in each bank of the DataBuffer.  
numBanks - The number of banks in the DataBuffer.

---

#### DataBufferFloat

public **DataBufferFloat**(float[] dataArray,  
int size)  
Constructs a float-based DataBuffer with the specified data array. Only the first size elements are available for use by this DataBuffer. The array must be large enough to hold size elements.  
**Parameters:**  
dataArray - An array of floats to be used as the first and only bank of this DataBuffer.  
size - The number of elements of the array to be used.

---

## DataBufferFloat

```
public DataBufferFloat(float[] dataArray,  
                       int size,  
                       int offset)
```

Constructs a float-based DataBuffer with the specified data array. Only the elements between offset and offset + size - 1 are available for use by this DataBuffer. The array must be large enough to hold offset + size elements.

**Parameters:**

dataArray - An array of floats to be used as the first and only bank of this DataBuffer.

size - The number of elements of the array to be used.

offset - The offset of the first element of the array that will be used.

---

## DataBufferFloat

```
public DataBufferFloat(float[][] dataArray,  
                       int size)
```

Constructs a float-based DataBuffer with the specified data arrays. Only the first size elements of each array are available for use by this DataBuffer. The number of banks will be equal to dataArray.length.

**Parameters:**

dataArray - An array of arrays of floats to be used as the banks of this DataBuffer.

size - The number of elements of each array to be used.

---

## DataBufferFloat

```
public DataBufferFloat(float[][] dataArray,  
                       int size,  
                       int[] offsets)
```

Constructs a float-based DataBuffer with the specified data arrays, size, and per-bank offsets. The number of banks is equal to dataArray.length. Each array must be at least as large as size plus the corresponding offset. There must be an entry in the offsets array for each data array.

**Parameters:**

dataArray - An array of arrays of floats to be used as the banks of this DataBuffer.

size - The number of elements of each array to be used.

offsets - An array of integer offsets, one for each bank.

---

## Method Detail

### getData

```
public float[] getData()
```

Returns the default (first) float data array.

---

### getData

```
public float[] getData(int bank)
```

Returns the data array for the specified bank.

---

### getBankData

```
public float[][] getBankData()
```

Returns the data array for all banks.

---

### getElem

```
public int getElem(int i)
```

Returns the requested data array element from the first (default) bank as an int.

**Parameters:**

i - The desired data array element.

**Returns:**

The data entry as an int.

**Overrides:**

getElem in class java.awt.image.DataBuffer

---

## getElem

```
public int getElem(int bank,  
                  int i)
```

Returns the requested data array element from the specified bank as an int.

**Parameters:**

bank - The bank number.  
i - The desired data array element.

**Returns:**

The data entry as an int.

**Overrides:**

getElem in class java.awt.image.DataBuffer

---

## setElem

```
public void setElem(int i,  
                  int val)
```

Sets the requested data array element in the first (default) bank to the given int.

**Parameters:**

i - The desired data array element.  
val - The value to be set.

**Overrides:**

setElem in class java.awt.image.DataBuffer

---

## setElem

```
public void setElem(int bank,  
                  int i,  
                  int val)
```

Sets the requested data array element in the specified bank to the given int.

**Parameters:**

bank - The bank number.  
i - The desired data array element.  
val - The value to be set.

**Overrides:**

setElem in class java.awt.image.DataBuffer

---

## getElemFloat

```
public float getElemFloat(int i)
```

Returns the requested data array element from the first (default) bank as a float.

**Parameters:**

i - The desired data array element.

**Returns:**

The data entry as a float.

**Overrides:**

getElemFloat in class java.awt.image.DataBuffer

---

## getElemFloat

```
public float getElemFloat(int bank,  
                          int i)
```

Returns the requested data array element from the specified bank as a float.

**Parameters:**

bank - The bank number.  
i - The desired data array element.

**Returns:**

The data entry as a float.

**Overrides:**

getElemFloat in class java.awt.image.DataBuffer

---

## setElemFloat

```
public void setElemFloat(int i,  
                        float val)
```

Sets the requested data array element in the first (default) bank to the given float.

**Parameters:**

i - The desired data array element.  
val - The value to be set.

**Overrides:**

setElemFloat in class java.awt.image.DataBuffer

---

## setElemFloat

```
public void setElemFloat(int bank,  
                        int i,  
                        float val)
```

Sets the requested data array element in the specified bank to the given float.

**Parameters:**

bank - The bank number.  
i - The desired data array element.  
val - The value to be set.

**Overrides:**

setElemFloat in class java.awt.image.DataBuffer

---

## getElemDouble

```
public double getElemDouble(int i)
```

Returns the requested data array element from the first (default) bank as a double.

**Parameters:**

i - The desired data array element.

**Returns:**

The data entry as a double.

**Overrides:**

getElemDouble in class java.awt.image.DataBuffer

---

## getElemDouble

```
public double getElemDouble(int bank,  
                        int i)
```

Returns the requested data array element from the specified bank as a double.

**Parameters:**

bank - The bank number.  
i - The desired data array element.

**Returns:**

The data entry as a double.

**Overrides:**

getElemDouble in class java.awt.image.DataBuffer

---

## setElemDouble

```
public void setElemDouble(int i,  
                        double val)
```

Sets the requested data array element in the first (default) bank to the given double.

**Parameters:**

i - The desired data array element.  
val - The value to be set.

**Overrides:**

setElemDouble in class java.awt.image.DataBuffer

---

## **setElemDouble**

```
public void setElemDouble(int bank,  
                           int i,  
                           double val)
```

Sets the requested data array element in the specified bank to the given double.

### **Parameters:**

bank - The bank number.  
i - The desired data array element.  
val - The value to be set.

### **Overrides:**

setElemDouble in class java.awt.image.DataBuffer

---

## javax.media.jai Class FloatDoubleColorModel

```
java.lang.Object
|
+-- java.awt.image.ColorModel
|   |
|   +-- java.awt.image.ComponentColorModel
|       |
|       +-- javax.media.jai.FloatDoubleColorModel
```

---

```
public class FloatDoubleColorModel
    extends java.awt.image.ComponentColorModel
```

A `ColorModel` class that works with pixel values that represent color and alpha information as separate samples, using float or double elements. This class can be used with an arbitrary `ColorSpace`. The number of color samples in the pixel values must be same as the number of color components in the `ColorSpace`. There may be a single alpha sample.

Sample values are taken as ranging from 0.0 to 1.0; that is, when converting to 8-bit RGB, a multiplication by 255 is performed and values outside of the range 0-255 are clamped at the closest endpoint.

For maximum efficiency, pixel data being interpreted by this class should be in the sRGB color space. This will result in only the trivial conversion (scaling by 255 and dividing by any premultiplied alpha) to be performed. Other color spaces require more general conversions.

For those methods that use a primitive array pixel representation of type `transferType`, the array length is the same as the number of color and alpha samples. Color samples are stored first in the array followed by the alpha sample, if present. The order of the color samples is specified by the `ColorSpace`. Typically, this order reflects the name of the color space type. For example, for `TYPE_RGB`, index 0 corresponds to red, index 1 to green, and index 2 to blue. The transfer types supported are `DataBuffer.TYPE_FLOAT`, `DataBuffer.TYPE_DOUBLE`.

The translation from pixel values to color/alpha components for display or processing purposes is a one-to-one correspondence of samples to components.

Methods that use a single int pixel representation throw an `IllegalArgumentException`.

A `FloatDoubleColorModel` can be used in conjunction with a `ComponentSampleModelJAI`.

## Field Detail

### colorSpace

```
java.awt.color.ColorSpace colorSpace
```

---

### colorSpaceType

```
int colorSpaceType
```

---

### numColorComponents

```
int numColorComponents
```

---

### numComponents

```
int numComponents
```

---

### transparency

```
int transparency
```

---

## hasAlpha

boolean **hasAlpha**

---

## isAlphaPremultiplied

boolean **isAlphaPremultiplied**

---

### Constructor Detail

#### FloatDoubleColorModel

```
public FloatDoubleColorModel(java.awt.color.ColorSpace colorSpace,  
                             boolean hasAlpha,  
                             boolean isAlphaPremultiplied,  
                             int transparency,  
                             int transferType)
```

Constructs a `ComponentColorModel` from the specified parameters. Color components will be in the specified `ColorSpace`. `hasAlpha` indicates whether alpha information is present. If `hasAlpha` is true, then the boolean `isAlphaPremultiplied` specifies how to interpret color and alpha samples in pixel values. If the boolean is true, color samples are assumed to have been multiplied by the alpha sample. The `transparency` specifies what alpha values can be represented by this color model. The `transferType` is the type of primitive array used to represent pixel values.

**Parameters:**

`colorSpace` - The `ColorSpace` associated with this color model.  
`hasAlpha` - If true, this color model supports alpha.  
`isAlphaPremultiplied` - If true, alpha is premultiplied.  
`transparency` - Specifies what alpha values can be represented by this color model.  
`transferType` - Specifies the type of primitive array used to represent pixel values, one of `DataBuffer.TYPE_FLOAT` or `TYPE_DOUBLE`.

**Throws:**

`java.lang.IllegalArgumentException` - If the transfer type is not `DataBuffer.TYPE_FLOAT` or `TYPE_DOUBLE`.

**See Also:**

`ColorSpace`, `Transparency`

---

### Method Detail

#### bitsHelper

```
private static int[] bitsHelper(int transferType,  
                                java.awt.color.ColorSpace colorSpace,  
                                boolean hasAlpha)
```

---

#### getRed

```
public int getRed(int pixel)
```

Throws an `IllegalArgumentException`, since pixel values for this `ColorModel` are not conveniently representable as a single int.

**Overrides:**

`getRed` in class `java.awt.image.ComponentColorModel`

---

#### getGreen

```
public int getGreen(int pixel)
```

Throws an `IllegalArgumentException`, since pixel values for this `ColorModel` are not conveniently representable as a single int.

**Overrides:**

`getGreen` in class `java.awt.image.ComponentColorModel`

---

#### getBlue

```
public int getBlue(int pixel)
```

Throws an `IllegalArgumentException`, since pixel values for this `ColorModel` are not conveniently representable as a single int.

**Overrides:**

getBlue in class java.awt.image.ComponentColorModel

---

**getAlpha**

```
public int getAlpha(int pixel)
```

Throws an `IllegalArgumentException`, since pixel values for this `ColorModel` are not conveniently representable as a single int.

**Overrides:**

getAlpha in class java.awt.image.ComponentColorModel

---

**getRGB**

```
public int getRGB(int pixel)
```

Throws an `IllegalArgumentException`, since pixel values for this `ColorModel` are not conveniently representable as a single int.

**Overrides:**

getRGB in class java.awt.image.ComponentColorModel

---

**clamp**

```
private int clamp(float value)
```

---

**clamp**

```
private int clamp(double value)
```

---

**getSample**

```
private int getSample(java.lang.Object inData,  
                      int sample)
```

---

**getRed**

```
public int getRed(java.lang.Object inData)
```

Returns the red color component for the specified pixel, scaled from 0 to 255 in the default RGB ColorSpace, sRGB. A color conversion is done if necessary. The `pixel` value is specified by an array of data elements of type `transferType` passed in as an object reference. The returned value will be a non pre-multiplied value. If the alpha is premultiplied, this method divides it out before returning the value (if the alpha value is 0, the red value will be 0).

**Parameters:**

`inData` - The pixel from which you want to get the red color component, specified by an array of data elements of type `transferType`.

**Returns:**

The red color component for the specified pixel, as an int.

**Throws:**

`ClassCastException` - If `inData` is not a primitive array of type `transferType`.

`ArrayIndexOutOfBoundsException` - if `inData` is not large enough to hold a pixel value for this `ColorModel`.

**Overrides:**

getRed in class java.awt.image.ComponentColorModel

---

**getGreen**

```
public int getGreen(java.lang.Object inData)
```

Returns the green color component for the specified pixel, scaled from 0 to 255 in the default RGB ColorSpace, sRGB. A color conversion is done if necessary. The `pixel` value is specified by an array of data elements of type `transferType` passed in as an object reference. The returned value will be a non pre-multiplied value. If the alpha is premultiplied, this method divides it out before returning the value (if the alpha value is 0, the green value will be 0).

**Parameters:**

`inData` - The pixel from which you want to get the green color component, specified by an array of data elements of type `transferType`.

**Returns:**

The green color component for the specified pixel, as an int.

**Throws:**

ClassCastException - If `inData` is not a primitive array of type `transferType`.

ArrayIndexOutOfBoundsException - if `inData` is not large enough to hold a pixel value for this `ColorModel`.

**Overrides:**

`getGreen` in class `java.awt.image.ComponentColorModel`

---

**getBlue**

```
public int getBlue(java.lang.Object inData)
```

Returns the blue color component for the specified pixel, scaled from 0 to 255 in the default RGB ColorSpace, sRGB. A color conversion is done if necessary. The `pixel` value is specified by an array of data elements of type `transferType` passed in as an object reference. The returned value will be a non pre-multiplied value. If the alpha is premultiplied, this method divides it out before returning the value (if the alpha value is 0, the blue value will be 0).

**Parameters:**

`inData` - The pixel from which you want to get the blue color component, specified by an array of data elements of type `transferType`.

**Returns:**

The blue color component for the specified pixel, as an int.

**Throws:**

ClassCastException - If `inData` is not a primitive array of type `transferType`.

ArrayIndexOutOfBoundsException - if `inData` is not large enough to hold a pixel value for this `ColorModel`.

**Overrides:**

`getBlue` in class `java.awt.image.ComponentColorModel`

---

**getAlpha**

```
public int getAlpha(java.lang.Object inData)
```

Returns the alpha component for the specified pixel, scaled from 0 to 255. The pixel value is specified by an array of data elements of type `transferType` passed in as an object reference. If the `ColorModel` does not have alpha, 255 is returned.

**Parameters:**

`inData` - The pixel from which you want to get the alpha component, specified by an array of data elements of type `transferType`.

**Returns:**

The alpha component for the specified pixel, as an int.

**Throws:**

NullPointerException - if `inData` is null and the `colorModel` has alpha.

ClassCastException - If `inData` is not a primitive array of type `transferType` and the `ColorModel` has alpha.

ArrayIndexOutOfBoundsException - if `inData` is not large enough to hold a pixel value for this `ColorModel` and the `ColorModel` has alpha.

**Overrides:**

`getAlpha` in class `java.awt.image.ComponentColorModel`

---

**getRGB**

```
public int getRGB(java.lang.Object inData)
```

Returns the color/alpha components for the specified pixel in the default RGB color model format. A color conversion is done if necessary. The pixel value is specified by an array of data elements of type `transferType` passed in as an object reference. The returned value is in a non pre-multiplied format. If the alpha is premultiplied, this method divides it out of the color components (if the alpha value is 0, the color values will be 0).

**Parameters:**

`inData` - The pixel from which you want to get the color/alpha components, specified by an array of data elements of type `transferType`.

**Returns:**

The color/alpha components for the specified pixel, as an int.

**Throws:**

ClassCastException - If `inData` is not a primitive array of type `transferType`.

ArrayIndexOutOfBoundsException - if `inData` is not large enough to hold a pixel value for this `ColorModel`.

**Overrides:**

`getRGB` in class `java.awt.image.ComponentColorModel`

---

## getDataElements

```
public java.lang.Object getDataElements(int rgb,  
                                         java.lang.Object pixel)
```

Returns a data element array representation of a pixel in this `ColorModel`, given an integer pixel representation in the default RGB color model. This array can then be passed to the `setDataElements` method of a `WritableRaster` object. If the `pixel` parameter is null, a new array is allocated.

**Parameters:**

`rgb` - An ARGB value packed into an int.  
`pixel` - The float or double array representation of the pixel.

**Throws:**

`ClassCastException` - If `pixel` is not null and is not a primitive array of type `transferType`.  
`ArrayIndexOutOfBoundsException` - If `pixel` is not large enough to hold a pixel value for this `ColorModel`.

**Overrides:**

`getDataElements` in class `java.awt.image.ComponentColorModel`

---

## getComponents

```
public int[] getComponents(int pixel,  
                           int[] components,  
                           int offset)
```

Throws an `IllegalArgumentException`, since pixel values for this `ColorModel` are not conveniently representable as a single int.

**Overrides:**

`getComponents` in class `java.awt.image.ComponentColorModel`

---

## getComponents

```
public int[] getComponents(java.lang.Object pixel,  
                           int[] components,  
                           int offset)
```

Throws an `IllegalArgumentException` since the pixel values cannot be placed into an int array.

**Overrides:**

`getComponents` in class `java.awt.image.ComponentColorModel`

---

## getDataElement

```
public int getDataElement(int[] components,  
                          int offset)
```

Throws an `IllegalArgumentException`, since pixel values for this `ColorModel` are not conveniently representable as a single int.

**Overrides:**

`getDataElement` in class `java.awt.image.ComponentColorModel`

---

## getDataElements

```
public java.lang.Object getDataElements(int[] components,  
                                         int offset,  
                                         java.lang.Object obj)
```

Returns a data element array representation of a pixel in this `ColorModel`, given an array of unnormalized color/alpha components. This array can then be passed to the `setDataElements` method of a `WritableRaster` object.

**Parameters:**

`components` - An array of unnormalized color/alpha components.  
`offset` - The integer offset into the `components` array.  
`obj` - The object in which to store the data element array representation of the pixel. If `obj` variable is null, a new array is allocated. If `obj` is not null, it must be a primitive array of type `transferType`. An `ArrayIndexOutOfBoundsException` is thrown if `obj` is not large enough to hold a pixel value for this `ColorModel`.

**Returns:**

The data element array representation of a pixel in this `ColorModel`.

**Throws:**

`java.lang.IllegalArgumentException` - If the `components` array is not large enough to hold all the color and alpha components (starting at `offset`).  
`ClassCastException` - If `obj` is not null and is not a primitive array of type `transferType`.  
`ArrayIndexOutOfBoundsException` - If `obj` is not large enough to hold a pixel value for this `ColorModel`.

**Overrides:**

getDataElements in class java.awt.image.ComponentColorModel

---

**coerceData**

```
public java.awt.image.ColorModel coerceData(java.awt.image.WritableRaster raster,  
                                             boolean isAlphaPremultiplied)
```

Forces the raster data to match the state specified in the isAlphaPremultiplied variable, assuming the data is currently correctly described by this ColorModel. It may multiply or divide the color raster data by alpha, or do nothing if the data is in the correct state. If the data needs to be coerced, this method also returns an instance of FloatDoubleColorModel with the isAlphaPremultiplied flag set appropriately.

**Throws:**

java.lang.IllegalArgumentException - if transfer type of raster is not the same as that of this FloatDoubleColorModel.

**Overrides:**

coerceData in class java.awt.image.ComponentColorModel

---

**isCompatibleRaster**

```
public boolean isCompatibleRaster(java.awt.image.Raster raster)
```

Returns true if the supplied Raster's SampleModel is compatible with this FloatDoubleColorModel.

**Parameters:**

raster - a Raster to be checked for compatibility.

**Overrides:**

isCompatibleRaster in class java.awt.image.ComponentColorModel

---

**createCompatibleWritableRaster**

```
public java.awt.image.WritableRaster createCompatibleWritableRaster(int w,  
                                                                    int h)
```

Creates a WritableRaster with the specified width and height, that has a data layout (SampleModel) compatible with this ColorModel. The returned WritableRaster's SampleModel will be an instance of ComponentSampleModel.

**Parameters:**

w - The width of the WritableRaster you want to create.

h - The height of the WritableRaster you want to create.

**Returns:**

A WritableRaster that is compatible with this ColorModel.

**Overrides:**

createCompatibleWritableRaster in class java.awt.image.ComponentColorModel

**See Also:**

WritableRaster, SampleModel

---

**createCompatibleSampleModel**

```
public java.awt.image.SampleModel createCompatibleSampleModel(int w,  
                                                                int h)
```

Creates a SampleModel with the specified width and height that has a data layout compatible with this ColorModel. The returned SampleModel will be an instance of ComponentSampleModel.

**Parameters:**

w - The width of the SampleModel you want to create.

h - The height of the SampleModel you want to create.

**Returns:**

A SampleModel that is compatible with this ColorModel.

**Overrides:**

createCompatibleSampleModel in class java.awt.image.ComponentColorModel

**See Also:**

SampleModel, ComponentSampleModel

---

## **isCompatibleSampleModel**

public boolean **isCompatibleSampleModel**(java.awt.image.SampleModel sm)

Checks whether or not the specified SampleModel is compatible with this ColorModel. A SampleModel is compatible if it is an instance of ComponentSampleModel, has the sample number of bands as the total number of components (including alpha) in the ColorSpace used by this ColorModel, and has the same data type (float or double) as this ColorModel.

**Parameters:**

sm - The SampleModel to test for compatibility.

**Returns:**

true if the SampleModel is compatible with this ColorModel, false if it is not.

**Overrides:**

isCompatibleSampleModel in class java.awt.image.ComponentColorModel

**See Also:**

SampleModel, ComponentSampleModel

---

## **toString**

public java.lang.String **toString**()

Returns a String containing the values of all valid fields.

**Overrides:**

toString in class java.awt.image.ColorModel

---

## javax.media.jai Class GraphicsJAI

```
java.lang.Object
|
+-- java.awt.Graphics
|   |
|   +-- java.awt.Graphics2D
|       |
|       +-- javax.media.jai.GraphicsJAI
```

---

public class **GraphicsJAI**  
extends java.awt.Graphics2D

A JAI wrapper for a Graphics2D object derived from a Component. When drawing JAI images to a Component such as a Canvas, a new GraphicsJAI may be constructed to wrap the Graphics2D object provided by that Component. This GraphicsJAI object may provide acceleration for calls to drawRenderedImage(), drawRenderableImage(), and possibly other methods.

If it is possible to use a CanvasJAI object instead of a generic Canvas, or other Canvas subclass, then the Graphics objects obtained from getGraphics() or received as an argument in paint() will automatically be instances of GraphicsJAI.

The portion of the GraphicsJAI interface that deals with adding and retrieving new hardware-specific implementations has not been finalized and does not appear in the current API.

## Field Detail

### g

java.awt.Graphics2D **g**

---

### component

java.awt.Component **component**

---

## Constructor Detail

### GraphicsJAI

```
protected GraphicsJAI(java.awt.Graphics2D g,  
                      java.awt.Component component)
```

Constructs a new instance of GraphicsJAI that wraps a given instance of Graphics2D for drawing to a given Component.

## Method Detail

### createGraphicsJAI

```
public static GraphicsJAI createGraphicsJAI(java.awt.Graphics2D g,  
                                             java.awt.Component component)
```

Returns an instance of GraphicsJAI suitable for rendering to the given Component via the given Graphics2D instance.

If one is available, this method will select a hardware-specific implementation, that is specialized for the display device containing the component.

---

### create

```
public java.awt.Graphics create()
```

Creates a new GraphicsJAI object that is a copy of this GraphicsJAI object.

#### Overrides:

create in class java.awt.Graphics

#### See Also:

Graphics.create()

---

## getColor

public java.awt.Color **getColor**()  
See comments in java.awt.Graphics.  
**Overrides:**  
getColor in class java.awt.Graphics  
**See Also:**  
Graphics.getColor()

---

## setColor

public void **setColor**(java.awt.Color c)  
See comments in java.awt.Graphics.  
**Overrides:**  
setColor in class java.awt.Graphics  
**See Also:**  
Graphics.setColor(Color)

---

## setPaintMode

public void **setPaintMode**()  
See comments in java.awt.Graphics.  
**Overrides:**  
setPaintMode in class java.awt.Graphics  
**See Also:**  
Graphics.setPaintMode()

---

## setXORMode

public void **setXORMode**(java.awt.Color c1)  
See comments in java.awt.Graphics.  
**Overrides:**  
setXORMode in class java.awt.Graphics  
**See Also:**  
Graphics.setXORMode(Color)

---

## getFont

public java.awt.Font **getFont**()  
See comments in java.awt.Graphics.  
**Overrides:**  
getFont in class java.awt.Graphics  
**See Also:**  
Graphics.getFont()

---

## setFont

public void **setFont**(java.awt.Font font)  
See comments in java.awt.Graphics.  
**Overrides:**  
setFont in class java.awt.Graphics  
**See Also:**  
Graphics.setFont(Font)

---

## getFontMetrics

public java.awt.FontMetrics **getFontMetrics**(java.awt.Font f)  
See comments in java.awt.Graphics.  
**Overrides:**  
getFontMetrics in class java.awt.Graphics

**See Also:**

Graphics.getFontMetrics(Font)

---

## getClipBounds

public java.awt.Rectangle **getClipBounds**()

See comments in java.awt.Graphics.

**Overrides:**

getClipBounds in class java.awt.Graphics

**See Also:**

Graphics.getClipBounds()

---

## clipRect

public void **clipRect**(int x,  
int y,  
int width,  
int height)

See comments in java.awt.Graphics.

**Overrides:**

clipRect in class java.awt.Graphics

**See Also:**

Graphics.clipRect(int, int, int, int)

---

## setClip

public void **setClip**(int x,  
int y,  
int width,  
int height)

See comments in java.awt.Graphics.

**Overrides:**

setClip in class java.awt.Graphics

**See Also:**

Graphics.setClip(int, int, int, int)

---

## getClip

public java.awt.Shape **getClip**()

See comments in java.awt.Graphics.

**Overrides:**

getClip in class java.awt.Graphics

**See Also:**

Graphics.getClip()

---

## setClip

public void **setClip**(java.awt.Shape clip)

See comments in java.awt.Graphics.

**Overrides:**

setClip in class java.awt.Graphics

**See Also:**

Graphics.setClip(Shape)

---

## copyArea

public void **copyArea**(int x,  
int y,  
int width,  
int height,  
int dx,  
int dy)

See comments in java.awt.Graphics.

**Overrides:**

copyArea in class java.awt.Graphics

**See Also:**

Graphics.copyArea(int, int, int, int, int, int)

---

## drawLine

```
public void drawLine(int x1,
                    int y1,
                    int x2,
                    int y2)
```

See comments in java.awt.Graphics.

**Overrides:**

drawLine in class java.awt.Graphics

**See Also:**

Graphics.drawLine(int, int, int, int)

---

## fillRect

```
public void fillRect(int x,
                    int y,
                    int width,
                    int height)
```

See comments in java.awt.Graphics.

**Overrides:**

fillRect in class java.awt.Graphics

**See Also:**

Graphics.fillRect(int, int, int, int)

---

## clearRect

```
public void clearRect(int x,
                     int y,
                     int width,
                     int height)
```

See comments in java.awt.Graphics.

**Overrides:**

clearRect in class java.awt.Graphics

**See Also:**

Graphics.clearRect(int, int, int, int)

---

## drawRoundRect

```
public void drawRoundRect(int x,
                         int y,
                         int width,
                         int height,
                         int arcWidth,
                         int arcHeight)
```

See comments in java.awt.Graphics.

**Overrides:**

drawRoundRect in class java.awt.Graphics

**See Also:**

Graphics.drawRoundRect(int, int, int, int, int, int)

---

## fillRoundRect

```
public void fillRoundRect(int x,
                        int y,
                        int width,
                        int height,
                        int arcWidth,
                        int arcHeight)
```

See comments in java.awt.Graphics.

**Overrides:**

fillRoundRect in class java.awt.Graphics

**See Also:**

Graphics.fillRoundRect(int, int, int, int, int, int)

---

## drawOval

```
public void drawOval(int x,
                    int y,
                    int width,
                    int height)
```

See comments in java.awt.Graphics.

**Overrides:**

drawOval in class java.awt.Graphics

**See Also:**

Graphics.drawOval(int, int, int, int)

---

## fillOval

```
public void fillOval(int x,
                    int y,
                    int width,
                    int height)
```

See comments in java.awt.Graphics.

**Overrides:**

fillOval in class java.awt.Graphics

**See Also:**

Graphics.fillOval(int, int, int, int)

---

## drawArc

```
public void drawArc(int x,
                   int y,
                   int width,
                   int height,
                   int startAngle,
                   int arcAngle)
```

See comments in java.awt.Graphics.

**Overrides:**

drawArc in class java.awt.Graphics

**See Also:**

Graphics.drawArc(int, int, int, int, int, int)

---

## fillArc

```
public void fillArc(int x,
                   int y,
                   int width,
                   int height,
                   int startAngle,
                   int arcAngle)
```

See comments in java.awt.Graphics.

**Overrides:**

fillArc in class java.awt.Graphics

**See Also:**

Graphics.fillArc(int, int, int, int, int, int)

---

## drawPolyline

```
public void drawPolyline(int[] xPoints,
                        int[] yPoints,
                        int nPoints)
```

See comments in java.awt.Graphics.

**Overrides:**

drawPolyline in class java.awt.Graphics

**See Also:**

Graphics.drawPolyline(int[], int[], int)

---

## drawPolygon

```
public void drawPolygon(int[] xPoints,  
                        int[] yPoints,  
                        int nPoints)
```

See comments in java.awt.Graphics.

**Overrides:**

drawPolygon in class java.awt.Graphics

**See Also:**

Graphics.drawPolygon(int[], int[], int)

---

## fillPolygon

```
public void fillPolygon(int[] xPoints,  
                        int[] yPoints,  
                        int nPoints)
```

See comments in java.awt.Graphics.

**Overrides:**

fillPolygon in class java.awt.Graphics

**See Also:**

Graphics.fillPolygon(int[], int[], int)

---

## drawImage

```
public boolean drawImage(java.awt.Image img,  
                          int x,  
                          int y,  
                          java.awt.image.ImageObserver observer)
```

See comments in java.awt.Graphics.

**Overrides:**

drawImage in class java.awt.Graphics

**See Also:**

Graphics.drawImage(Image, int, int, ImageObserver)

---

## drawImage

```
public boolean drawImage(java.awt.Image img,  
                          int x,  
                          int y,  
                          int width,  
                          int height,  
                          java.awt.image.ImageObserver observer)
```

See comments in java.awt.Graphics.

**Overrides:**

drawImage in class java.awt.Graphics

**See Also:**

Graphics.drawImage(Image, int, int, int, int, ImageObserver)

---

## drawImage

```
public boolean drawImage(java.awt.Image img,  
                          int x,  
                          int y,  
                          java.awt.Color bgcolor,  
                          java.awt.image.ImageObserver observer)
```

See comments in java.awt.Graphics.

**Overrides:**

drawImage in class java.awt.Graphics

**See Also:**

Graphics.drawImage(Image, int, int, Color, ImageObserver)

---

## drawImage

```
public boolean drawImage(java.awt.Image img,
                          int x,
                          int y,
                          int width,
                          int height,
                          java.awt.Color bgcolor,
                          java.awt.image.ImageObserver observer)
```

See comments in java.awt.Graphics.

**Overrides:**

drawImage in class java.awt.Graphics

**See Also:**

Graphics.drawImage(Image, int, int, int, int, Color, ImageObserver)

---

## drawImage

```
public boolean drawImage(java.awt.Image img,
                          int dx1,
                          int dy1,
                          int dx2,
                          int dy2,
                          int sx1,
                          int sy1,
                          int sx2,
                          int sy2,
                          java.awt.image.ImageObserver observer)
```

See comments in java.awt.Graphics.

**Overrides:**

drawImage in class java.awt.Graphics

**See Also:**

Graphics.drawImage(Image, int, int, int, int, int, int, int, int, ImageObserver)

---

## drawImage

```
public boolean drawImage(java.awt.Image img,
                          int dx1,
                          int dy1,
                          int dx2,
                          int dy2,
                          int sx1,
                          int sy1,
                          int sx2,
                          int sy2,
                          java.awt.Color bgcolor,
                          java.awt.image.ImageObserver observer)
```

See comments in java.awt.Graphics.

**Overrides:**

drawImage in class java.awt.Graphics

**See Also:**

Graphics.drawImage(Image, int, int, int, int, int, int, int, int, Color, ImageObserver)

---

## dispose

```
public void dispose()
```

See comments in java.awt.Graphics.

**Overrides:**

dispose in class java.awt.Graphics

**See Also:**

Graphics.dispose()

---

## draw

public void **draw**(java.awt.Shape s)

See comments in java.awt.Graphics2D.

**Overrides:**

draw in class java.awt.Graphics2D

**See Also:**

Graphics2D.draw(Shape)

---

## drawImage

public boolean **drawImage**(java.awt.Image img,  
java.awt.geom.AffineTransform xform,  
java.awt.image.ImageObserver obs)

See comments in java.awt.Graphics2D.

**Overrides:**

drawImage in class java.awt.Graphics2D

**See Also:**

Graphics2D.drawImage(Image, AffineTransform, ImageObserver)

---

## drawImage

public void **drawImage**(java.awt.image.BufferedImage img,  
java.awt.image.BufferedImageOp op,  
int x,  
int y)

See comments in java.awt.Graphics2D.

**Overrides:**

drawImage in class java.awt.Graphics2D

**See Also:**

Graphics2D.drawImage(BufferedImage, BufferedImageOp, int, int)

---

## drawRenderedImage

public void **drawRenderedImage**(java.awt.image.RenderedImage img,  
java.awt.geom.AffineTransform xform)

See comments in java.awt.Graphics2D.

**Overrides:**

drawRenderedImage in class java.awt.Graphics2D

**See Also:**

Graphics2D.drawRenderedImage(RenderedImage, AffineTransform)

---

## drawRenderableImage

public void **drawRenderableImage**(java.awt.image.renderable.RenderableImage img,  
java.awt.geom.AffineTransform xform)

See comments in java.awt.Graphics2D.

**Overrides:**

drawRenderableImage in class java.awt.Graphics2D

**See Also:**

Graphics2D.drawRenderableImage(RenderableImage, AffineTransform)

---

## drawString

public void **drawString**(java.lang.String str,  
int x,  
int y)

See comments in java.awt.Graphics2D.

**Overrides:**

drawString in class java.awt.Graphics2D

**See Also:**

Graphics2D.drawString(String, int, int)

---

## drawString

```
public void drawString(java.lang.String s,  
                      float x,  
                      float y)
```

See comments in java.awt.Graphics2D.

**Overrides:**

drawString in class java.awt.Graphics2D

**See Also:**

Graphics2D.drawString(String, float, float)

---

## drawString

```
public void drawString(java.text.AttributedString iterator,  
                      int x,  
                      int y)
```

See comments in java.awt.Graphics2D.

**Overrides:**

drawString in class java.awt.Graphics2D

**See Also:**

Graphics2D.drawString(AttributedString, int, int)

---

## drawString

```
public void drawString(java.text.AttributedString iterator,  
                      float x,  
                      float y)
```

See comments in java.awt.Graphics2D.

**Overrides:**

drawString in class java.awt.Graphics2D

**See Also:**

Graphics2D.drawString(AttributedString, float, float)

---

## drawGlyphVector

```
public void drawGlyphVector(java.awt.font.GlyphVector g,  
                             float x,  
                             float y)
```

See comments in java.awt.Graphics2D.

**Overrides:**

drawGlyphVector in class java.awt.Graphics2D

**See Also:**

Graphics2D.drawGlyphVector(GlyphVector, float, float)

---

## fill

```
public void fill(java.awt.Shape s)
```

See comments in java.awt.Graphics2D.

**Overrides:**

fill in class java.awt.Graphics2D

**See Also:**

Graphics2D.fill(Shape)

---

## hit

```
public boolean hit(java.awt.Rectangle rect,  
                  java.awt.Shape s,  
                  boolean onStroke)
```

See comments in java.awt.Graphics2D.

**Overrides:**

hit in class java.awt.Graphics2D

**See Also:**

Graphics2D.hit(Rectangle, Shape, boolean)

---

## getDeviceConfiguration

public java.awt.GraphicsConfiguration **getDeviceConfiguration**()

See comments in java.awt.Graphics2D.

**Overrides:**

getDeviceConfiguration in class java.awt.Graphics2D

**See Also:**

Graphics2D.getDeviceConfiguration()

---

## setComposite

public void **setComposite**(java.awt.Composite comp)

See comments in java.awt.Graphics2D.

**Overrides:**

setComposite in class java.awt.Graphics2D

**See Also:**

Graphics2D.setComposite(Composite)

---

## setPaint

public void **setPaint**(java.awt.Paint paint)

See comments in java.awt.Graphics2D.

**Overrides:**

setPaint in class java.awt.Graphics2D

**See Also:**

Graphics2D.setPaint(Paint)

---

## setStroke

public void **setStroke**(java.awt.Stroke s)

See comments in java.awt.Graphics2D.

**Overrides:**

setStroke in class java.awt.Graphics2D

**See Also:**

Graphics2D.setStroke(Stroke)

---

## setRenderingHint

public void **setRenderingHint**(java.awt.RenderingHints.Key hintKey,  
java.lang.Object hintValue)

See comments in java.awt.Graphics2D.

**Overrides:**

setRenderingHint in class java.awt.Graphics2D

**See Also:**

Graphics2D.setRenderingHint(RenderingHints.Key, Object)

---

## getRenderingHint

public java.lang.Object **getRenderingHint**(java.awt.RenderingHints.Key hintKey)

See comments in java.awt.Graphics2D.

**Overrides:**

getRenderingHint in class java.awt.Graphics2D

**See Also:**

Graphics2D.getRenderingHint(RenderingHints.Key)

---

## setRenderingHints

public void **setRenderingHints**(java.util.Map hints)

See comments in java.awt.Graphics2D.

**Overrides:**

setRenderingHints in class java.awt.Graphics2D

**See Also:**

`Graphics2D.setRenderingHints(Map)`

---

## **addRenderingHints**

public void **addRenderingHints**(java.util.Map hints)

See comments in java.awt.Graphics2D.

**Overrides:**

addRenderingHints in class java.awt.Graphics2D

**See Also:**

`Graphics2D.addRenderingHints(Map)`

---

## **getRenderingHints**

public java.awt.RenderingHints **getRenderingHints**()

See comments in java.awt.Graphics2D.

**Overrides:**

getRenderingHints in class java.awt.Graphics2D

**See Also:**

`Graphics2D.getRenderingHints()`

---

## **translate**

public void **translate**(int x,  
int y)

See comments in java.awt.Graphics2D.

**Overrides:**

translate in class java.awt.Graphics2D

**See Also:**

`Graphics2D.translate(int, int)`

---

## **translate**

public void **translate**(double tx,  
double ty)

See comments in java.awt.Graphics2D.

**Overrides:**

translate in class java.awt.Graphics2D

**See Also:**

`Graphics2D.translate(double, double)`

---

## **rotate**

public void **rotate**(double theta)

See comments in java.awt.Graphics2D.

**Overrides:**

rotate in class java.awt.Graphics2D

**See Also:**

`Graphics2D.rotate(double)`

---

## **rotate**

public void **rotate**(double theta,  
double x,  
double y)

See comments in java.awt.Graphics2D.

**Overrides:**

rotate in class java.awt.Graphics2D

**See Also:**

`Graphics2D.rotate(double, double, double)`

---

## scale

```
public void scale(double sx,  
                  double sy)
```

See comments in java.awt.Graphics2D.

**Overrides:**

scale in class java.awt.Graphics2D

**See Also:**

Graphics2D.scale(double, double)

---

## shear

```
public void shear(double shx,  
                  double shy)
```

See comments in java.awt.Graphics2D.

**Overrides:**

shear in class java.awt.Graphics2D

**See Also:**

Graphics2D.shear(double, double)

---

## transform

```
public void transform(java.awt.geom.AffineTransform Tx)
```

See comments in java.awt.Graphics2D.

**Overrides:**

transform in class java.awt.Graphics2D

**See Also:**

Graphics2D.transform(AffineTransform)

---

## setTransform

```
public void setTransform(java.awt.geom.AffineTransform Tx)
```

See comments in java.awt.Graphics2D.

**Overrides:**

setTransform in class java.awt.Graphics2D

**See Also:**

Graphics2D.setTransform(AffineTransform)

---

## getTransform

```
public java.awt.geom.AffineTransform getTransform()
```

See comments in java.awt.Graphics2D.

**Overrides:**

getTransform in class java.awt.Graphics2D

**See Also:**

Graphics2D.getTransform()

---

## getPaint

```
public java.awt.Paint getPaint()
```

See comments in java.awt.Graphics2D.

**Overrides:**

getPaint in class java.awt.Graphics2D

**See Also:**

Graphics2D.getPaint()

---

## getComposite

```
public java.awt.Composite getComposite()
```

See comments in java.awt.Graphics2D.

**Overrides:**

getComposite in class java.awt.Graphics2D

**See Also:**  
`Graphics2D.getComposite()`

---

## **setBackground**

public void **setBackground**(java.awt.Color color)  
See comments in java.awt.Graphics2D.  
**Overrides:**  
    setBackground in class java.awt.Graphics2D  
**See Also:**  
    Graphics2D.setBackground(Color)

---

## **getBackground**

public java.awt.Color **getBackground**()  
See comments in java.awt.Graphics2D.  
**Overrides:**  
    getBackground in class java.awt.Graphics2D  
**See Also:**  
    Graphics2D.getBackground()

---

## **getStroke**

public java.awt.Stroke **getStroke**()  
See comments in java.awt.Graphics2D.  
**Overrides:**  
    getStroke in class java.awt.Graphics2D  
**See Also:**  
    Graphics2D.getStroke()

---

## **clip**

public void **clip**(java.awt.Shape s)  
See comments in java.awt.Graphics2D.  
**Overrides:**  
    clip in class java.awt.Graphics2D  
**See Also:**  
    Graphics2D.clip(Shape)

---

## **getFontRenderContext**

public java.awt.font.FontRenderContext **getFontRenderContext**()  
See comments in java.awt.Graphics2D.  
**Overrides:**  
    getFontRenderContext in class java.awt.Graphics2D  
**See Also:**  
    Graphics2D.getFontRenderContext()

---

## javax.media.jai Class Histogram

java.lang.Object  
|-- javax.media.jai.Histogram

---

public class **Histogram**  
extends java.lang.Object  
implements java.io.Serializable

An object for accumulating histogram information on an image.

A histogram counts the number of image samples whose values lie within a given range of values, or "bin." The source image may be of any data type. Furthermore, the set of pixels counted may be limited by the use of a region of interest (ROI), and by horizontal and vertical subsampling factors. These factors allow the accuracy of the histogram to be traded for speed of computation.

The Histogram class is intended to be used mainly by the "Histogram" operation, which takes care of the details of taking a histogram of an entire (tiled) image.

### See Also:

HistogramDescriptor

---

## Field Detail

### numBands

private int **numBands**

The number of bands in the image which the histogram is taken.

---

### numBins

private int[] **numBins**

The number of bins used for each band of the image.

---

### lowValue

private double[] **lowValue**

The lowest pixel value of the image checked for each band.

---

### highValue

private double[] **highValue**

The highest pixel value of the image checked for each band.

---

### binWidth

private double[] **binWidth**

---

### bins

private int[][] **bins**

The bins for each band, used to hold information about pixel vlaues.

---

## Constructor Detail

### Histogram

```
public Histogram(int[] numBins,  
                 double[] lowValue,  
                 double[] highValue)
```

Constructs a Histogram that may be used to accumulate data within a given range for each band of an image. The legal pixel range and the number of bins may be controlled separately. If binWidth is defined as  $(\text{highValue} - \text{lowValue}) / \text{numBins}$ , bin  $i$  will count pixel values in the range from  $\text{lowValue} + i * \text{binWidth} \leq x < \text{lowValue} + (i + 1) * \text{binWidth}$ . Pixels that have values outside the range of lowValue and highValue, that is  $(\text{pixel} < \text{lowValue} \ \&\& \ \text{pixel} \geq \text{highValue})$ , are ignored.

**Parameters:**

numBins - The number of bins for each band of the image; numBins.length must be equal to the number of bands of the image which the histogram is taken.

lowValue - The lowest pixel value checked for each band.

highValue - The highest pixel value checked for each band. Note when counting the pixel values, this highValue is not included based on the above formula.

**Throws:**

NullPointerException - if numBins is null.

NullPointerException - if lowValue is null.

NullPointerException - if highValue is null.

java.lang.IllegalArgumentException - if either lowValue or highValue does not have the same number of elements as numBins

## Method Detail

### getNumBands

```
public int getNumBands()
```

Returns the number of bands of the histogram.

### getNumBins

```
public int[] getNumBins()
```

Returns the number of bins of the histogram for all bands.

### getNumBins

```
public int getNumBins(int band)
```

Returns the number of bins of the histogram for a specified band.

**Throws:**

ArrayIndexOutOfBoundsException - if an invalid band is specified.

### getLowValue

```
public double[] getLowValue()
```

Returns the lowest value checked for all bands.

### getLowValue

```
public double getLowValue(int band)
```

Returns the lowest value checked for a specified band.

**Throws:**

ArrayIndexOutOfBoundsException - if an invalid band is specified.

### getHighValue

```
public double[] getHighValue()
```

Returns the highest value checked for all bands.

### getHighValue

```
public double getHighValue(int band)
```

Returns the highest value checked for a specified band.

**Throws:**

ArrayIndexOutOfBoundsException - if an invalid band is specified.

---

## getBins

```
public int[][] getBins()
```

Returns the bins of the histogram for all bands.

---

## getBins

```
public int[] getBins(int band)
```

Returns the bins of the histogram for a specified band.

**Throws:**

ArrayIndexOutOfBoundsException - if an invalid band is specified.

---

## getBinSize

```
public int getBinSize(int band,  
                      int bin)
```

Returns the number of pixel values found in a given bin for a given band.

**Throws:**

ArrayIndexOutOfBoundsException - if an invalid band is specified.

ArrayIndexOutOfBoundsException - if an invalid bin is specified.

---

## getBinLowValue

```
public double getBinLowValue(int band,  
                             int bin)
```

Returns the lowest pixel value found in a given bin for a given band.

**Throws:**

ArrayIndexOutOfBoundsException - if an invalid band is specified.

---

## clearHistogram

```
public void clearHistogram()
```

Resets the counts of all bins to zero.

---

## countPixels

```
public void countPixels(java.awt.image.Raster pixels,  
                        ROI roi,  
                        int xStart,  
                        int yStart,  
                        int xPeriod,  
                        int yPeriod)
```

Adds the pixels of a Raster that lie within a given region of interest (ROI) to the histogram. The set of pixels is further reduced by subsampling factors in the horizontal and vertical directions. The set of pixels to be accumulated may be obtained by intersecting the grid (xStart + i\*xPeriod, yStart + j\*yPeriod); i, j >= 0 with the region of interest and the bounding rectangle of the Raster.

**Parameters:**

pixels - A Raster containing pixels to be histogrammed.

roi - The region of interest, as a ROI.

xStart - The initial X sample coordinate.

yStart - The initial Y sample coordinate.

xPeriod - The X sampling rate.

yPeriod - The Y sampling rate.

**Throws:**

NullPointerException - if pixels is null.

java.lang.IllegalArgumentException - if the source raster and the histogram object do not match in number of bands.

---

### **countPixelsByte**

```
private void countPixelsByte(RasterAccessor source,  
                             java.awt.Rectangle rect,  
                             int xPeriod,  
                             int yPeriod)
```

---

### **countPixelsUShort**

```
private void countPixelsUShort(RasterAccessor source,  
                               java.awt.Rectangle rect,  
                               int xPeriod,  
                               int yPeriod)
```

---

### **countPixelsShort**

```
private void countPixelsShort(RasterAccessor source,  
                              java.awt.Rectangle rect,  
                              int xPeriod,  
                              int yPeriod)
```

---

### **countPixelsInt**

```
private void countPixelsInt(RasterAccessor source,  
                            java.awt.Rectangle rect,  
                            int xPeriod,  
                            int yPeriod)
```

---

### **countPixelsFloat**

```
private void countPixelsFloat(RasterAccessor source,  
                              java.awt.Rectangle rect,  
                              int xPeriod,  
                              int yPeriod)
```

---

### **countPixelsDouble**

```
private void countPixelsDouble(RasterAccessor source,  
                               java.awt.Rectangle rect,  
                               int xPeriod,  
                               int yPeriod)
```

---

### **startPosition**

```
private int startPosition(int pos,  
                          int start,  
                          int Period)
```

---

## javax.media.jai Interface ImageFunction

---

public abstract interface **ImageFunction**

ImageFunction is a common interface for vector-valued functions which are to be evaluated at positions in the X-Y coordinate system. At each position the value of such a function may contain one or more elements each of which may be complex.

---

### Method Detail

#### isComplex

public boolean **isComplex**()

Returns whether or not each value's elements are complex.

---

#### getNumElements

public int **getNumElements**()

Returns the number of elements per value at each position.

---

#### getElements

```
public void getElements(float startX,
                        float startY,
                        float deltaX,
                        float deltaY,
                        int countX,
                        int countY,
                        int element,
                        float[] real,
                        float[] imag)
```

Returns all values of a given element for a specified set of coordinates. An `ArrayIndexOutOfBoundsException` may be thrown if the length of the supplied array(s) is insufficient.

**Parameters:**

startX - The X coordinate of the upper left location to evaluate.

startY - The Y coordinate of the upper left location to evaluate.

deltaX - The horizontal increment.

deltaY - The vertical increment.

countX - The number of points in the horizontal direction.

countY - The number of points in the vertical direction.

real - A pre-allocated float array of length at least countX\*countY in which the real parts of all elements will be returned.

imag - A pre-allocated float array of length at least countX\*countY in which the imaginary parts of all elements will be returned; may be null for real data, i.e., when `isComplex()` returns false.

**Throws:**

`ArrayIndexOutOfBoundsException` - if the length of the supplied array(s) is insufficient.

---

#### getElements

```
public void getElements(double startX,
                        double startY,
                        double deltaX,
                        double deltaY,
                        int countX,
                        int countY,
                        int element,
                        double[] real,
                        double[] imag)
```

Returns all values of a given element for a specified set of coordinates. An `ArrayIndexOutOfBoundsException` may be thrown if the length of the supplied array(s) is insufficient.

**Parameters:**

startX - The X coordinate of the upper left location to evaluate.

startY - The Y coordinate of the upper left location to evaluate.

deltaX - The horizontal increment.

`deltaY` - The vertical increment.

`countX` - The number of points in the horizontal direction.

`countY` - The number of points in the vertical direction.

`real` - A pre-allocated double array of length at least `countX*countY` in which the real parts of all elements will be returned.

`imag` - A pre-allocated double array of length at least `countX*countY` in which the imaginary parts of all elements will be returned; may be null for real data, i.e., when `isComplex()` returns false.

**Throws:**

`ArrayIndexOutOfBoundsException` - if the length of the supplied array(s) is insufficient.

---

**javax.media.jai**

## **Interface ImageJAI**

**All Known Implementing Classes:**

CollectionImage, ImageMIPMap, PlanarImage

---

public abstract interface **ImageJAI**

extends PropertySource

An interface implemented by all JAI image classes.

---

---

## javax.media.jai Class ImageLayout

java.lang.Object  
|  
+-- javax.media.jai.ImageLayout

---

public class **ImageLayout**  
extends java.lang.Object  
implements java.lang.Cloneable, java.io.Serializable  
A class describing the desired layout of an OpImage.

The ImageLayout class encapsulates three types of information about an image:

- The image bounds, comprising the min X and Y coordinates, image width, and image height;
- The tile grid layout, comprising the tile grid X and Y offsets, the tile width, and the tile height; and
- The SampleModel and ColorModel of the image.

Each of these parameters may be set individually, or left unset. An unset parameter will cause the corresponding value of a given RenderedImage to be used. For example, the code:

```
ImageLayout layout;  
RenderedImage im;  
  
int width = layout.getTileWidth(im);
```

will return the tile width of the ImageLayout if it is set, or the tile width of the image `im` if it is not.

ImageLayout objects are primarily intended to be passed as part of the `renderingHints` argument of the `create()` method of `RenderedImageFactory`. The `create()` method may remove parameter settings that it cannot deal with, prior to passing the ImageLayout to any OpImage constructors. New OpImage subclasses are not required to accept an ImageLayout parameter, but most will at least need to synthesize one to be passed up the constructor chain.

Methods that modify the state of an ImageLayout return a reference to 'this' following the change. This allows multiple modifications to be made in a single expression. This provides a way of modifying an ImageLayout within a superclass constructor call.

---

### Field Detail

#### MIN\_X\_MASK

public static final int **MIN\_X\_MASK**  
A bitmask to specify the validity of minX.

---

#### MIN\_Y\_MASK

public static final int **MIN\_Y\_MASK**  
A bitmask to specify the validity of minY.

---

#### WIDTH\_MASK

public static final int **WIDTH\_MASK**  
A bitmask to specify the validity of width.

---

#### HEIGHT\_MASK

public static final int **HEIGHT\_MASK**  
A bitmask to specify the validity of height.

---

#### TILE\_GRID\_X\_OFFSET\_MASK

public static final int **TILE\_GRID\_X\_OFFSET\_MASK**  
A bitmask to specify the validity of tileGridXOffset.

---

## **TILE\_GRID\_Y\_OFFSET\_MASK**

public static final int **TILE\_GRID\_Y\_OFFSET\_MASK**  
A bitmask to specify the validity of tileGridYOffset.

---

## **TILE\_WIDTH\_MASK**

public static final int **TILE\_WIDTH\_MASK**  
A bitmask to specify the validity of tileWidth.

---

## **TILE\_HEIGHT\_MASK**

public static final int **TILE\_HEIGHT\_MASK**  
A bitmask to specify the validity of tileHeight.

---

## **SAMPLE\_MODEL\_MASK**

public static final int **SAMPLE\_MODEL\_MASK**  
A bitmask to specify the validity of sampleModel.

---

## **COLOR\_MODEL\_MASK**

public static final int **COLOR\_MODEL\_MASK**  
A bitmask to specify the validity of colorModel.

---

## **minX**

int **minX**  
The image's minimum X coordinate.

---

## **minY**

int **minY**  
The image's minimum Y coordinate.

---

## **width**

int **width**  
The image's width.

---

## **height**

int **height**  
The image's height.

---

## **tileGridXOffset**

int **tileGridXOffset**  
The X coordinate of tile (0, 0).

---

## **tileGridYOffset**

int **tileGridYOffset**  
The Y coordinate of tile (0, 0).

---

## tileWidth

int **tileWidth**  
The width of a tile.

---

## tileHeight

int **tileHeight**  
The height of a tile.

---

## sampleModel

transient java.awt.image.SampleModel **sampleModel**  
The image's SampleModel.

---

## colorModel

transient java.awt.image.ColorModel **colorModel**  
The image's ColorModel.

---

## validMask

protected int **validMask**  
The 'or'-ed together valid bitmasks.

---

## Constructor Detail

### ImageLayout

public **ImageLayout**()  
Constructs an ImageLayout with no parameters set.

---

### ImageLayout

```
public ImageLayout(int minX,
                   int minY,
                   int width,
                   int height,
                   int tileGridXOffset,
                   int tileGridYOffset,
                   int tileWidth,
                   int tileHeight,
                   java.awt.image.SampleModel sampleModel,
                   java.awt.image.ColorModel colorModel)
```

Constructs an ImageLayout with all its parameters set. The sampleModel and colorModel parameters may be set to null, but are nonetheless considered 'set' in the sense that they will override the corresponding parameter in any RenderedImage.

#### Parameters:

- minX - the image's minimum X coordinate.
- minY - the image's minimum Y coordinate.
- width - the image's width.
- height - the image's height.
- tileGridXOffset - the X coordinate of tile (0, 0).
- tileGridYOffset - the Y coordinate of tile (0, 0).
- tileWidth - the width of a tile.
- tileHeight - the height of a tile.
- sampleModel - the image's SampleModel.
- colorModel - the image's ColorModel.

---

## ImageLayout

```
public ImageLayout(int minX,
                  int minY,
                  int width,
                  int height)
```

Constructs an ImageLayout with only the image dimension parameters set.

**Parameters:**

minX - the image's minimum X coordinate.  
minY - the image's minimum Y coordinate.  
width - the image's width.  
height - the image's height.

---

## ImageLayout

```
public ImageLayout(int tileGridXOffset,
                  int tileGridYOffset,
                  int tileWidth,
                  int tileHeight,
                  java.awt.image.SampleModel sampleModel,
                  java.awt.image.ColorModel colorModel)
```

Constructs an ImageLayout with its tile grid layout, SampleModel, and ColorModel parameters set. The sampleModel and colorModel parameters may be set to null, but are nonetheless considered 'set' in the sense that they will override the corresponding parameter in any RenderedImage.

**Parameters:**

tileGridXOffset - the X coordinate of tile (0, 0).  
tileGridYOffset - the Y coordinate of tile (0, 0).  
tileWidth - the width of a tile.  
tileHeight - the height of a tile.  
sampleModel - the image's SampleModel.  
colorModel - the image's ColorModel.

---

## ImageLayout

```
public ImageLayout(java.awt.image.RenderedImage im)
```

Constructs an ImageLayout with all its parameters set to equal those of a given RenderedImage.

**Parameters:**

im - a RenderedImage whose layout will be copied.

---

## Method Detail

### getValidMask

```
public int getValidMask()
```

Returns the 'or'-ed together bitmask indicating parameter validity. To determine the validity of a particular parameter, say tile width, test `getValidMask() & ImageLayout.TILE_WIDTH_MASK` against 0.

To test a single mask value or set of mask values, the convenience method `isValid()` may be used.

**Returns:**

an int that is the logical 'or' of the valid mask values, with a '1' bit representing the setting of a value.

---

### isValid

```
public final boolean isValid(int mask)
```

Returns true if all the parameters specified by the argument are set.

**Parameters:**

mask - a bitmask.

**Returns:**

a boolean truth value.

---

## setValid

```
public ImageLayout setValid(int mask)
```

Sets selected bits of the valid bitmask. The valid bitmask is set to the logical 'or' of its prior value and a new value.

**Parameters:**

mask - the new mask value to be 'or'-ed with the prior value.

**Returns:**

a reference to this ImageLayout following the change.

---

## unsetValid

```
public ImageLayout unsetValid(int mask)
```

Clears selected bits of the valid bitmask. The valid bitmask is set to the logical 'and' of its prior value and the negation of the new mask value. This effectively subtracts from the set of valid parameters.

**Parameters:**

mask - the new mask value to be negated and 'and'-ed with the prior value.

**Returns:**

a reference to this ImageLayout following the change.

---

## unsetImageBounds

```
public ImageLayout unsetImageBounds()
```

Marks the parameters dealing with the image bounds (minX, minY, width, and height) as being invalid.

**Returns:**

a reference to this ImageLayout following the change.

---

## unsetTileLayout

```
public ImageLayout unsetTileLayout()
```

Marks the parameters dealing with the tile layout (tileGridXOffset, tileGridYOffset, tileWidth, and tileHeight) as being invalid.

**Returns:**

a reference to this ImageLayout following the change.

---

## getMinX

```
public int getMinX(java.awt.image.RenderedImage fallback)
```

Returns the value of minX if it is valid, and otherwise returns the value from the supplied RenderedImage. If minX is not valid and fallback is null, 0 is returned.

**Parameters:**

fallback - the RenderedImage fallback.

**Returns:**

the appropriate value of minX.

---

## setMinX

```
public ImageLayout setMinX(int minX)
```

Sets minX to the supplied value and marks it as valid.

**Parameters:**

minX - the minimum X coordinate of the image, as an int.

**Returns:**

a reference to this ImageLayout following the change.

---

## getMinY

```
public int getMinY(java.awt.image.RenderedImage fallback)
```

Returns the value of minY if it is valid, and otherwise returns the value from the supplied RenderedImage. If minY is not valid and fallback is null, 0 is returned.

**Parameters:**

fallback - the RenderedImage fallback.

**Returns:**

the appropriate value of minY.

---

## setMinY

public ImageLayout **setMinY**(int minY)

Sets minY to the supplied value and marks it as valid.

**Parameters:**

minY - the minimum Y coordinate of the image, as an int.

**Returns:**

a reference to this ImageLayout following the change.

---

## getWidth

public int **getWidth**(java.awt.image.RenderedImage fallback)

Returns the value of width if it is valid, and otherwise returns the value from the supplied RenderedImage. If width is not valid and fallback is null, 0 is returned.

**Parameters:**

fallback - the RenderedImage fallback.

**Returns:**

the appropriate value of width.

---

## setWidth

public ImageLayout **setWidth**(int width)

Sets width to the supplied value and marks it as valid.

**Parameters:**

width - the width of the image, as an int.

**Returns:**

a reference to this ImageLayout following the change.

---

## getHeight

public int **getHeight**(java.awt.image.RenderedImage fallback)

Returns the value of height if it is valid, and otherwise returns the value from the supplied RenderedImage. If height is not valid and fallback is null, 0 is returned.

**Parameters:**

fallback - the RenderedImage fallback.

**Returns:**

the appropriate value of height.

---

## setHeight

public ImageLayout **setHeight**(int height)

Sets height to the supplied value and marks it as valid.

**Parameters:**

height - the height of the image, as an int.

**Returns:**

a reference to this ImageLayout following the change.

---

## getTileGridXOffset

public int **getTileGridXOffset**(java.awt.image.RenderedImage fallback)

Returns the value of tileGridXOffset if it is valid, and otherwise returns the value from the supplied RenderedImage. If tileGridXOffset is not valid and fallback is null, 0 is returned.

**Parameters:**

fallback - the RenderedImage fallback.

**Returns:**

the appropriate value of tileGridXOffset.

---

### setTileGridXOffset

```
public ImageLayout setTileGridXOffset(int tileGridXOffset)
```

Sets tileGridXOffset to the supplied value and marks it as valid.

**Parameters:**

tileGridXOffset - the X coordinate of tile (0, 0), as an int.

**Returns:**

a reference to this ImageLayout following the change.

---

### getTileGridYOffset

```
public int getTileGridYOffset(java.awt.image.RenderedImage fallback)
```

Returns the value of tileGridYOffset if it is valid, and otherwise returns the value from the supplied RenderedImage. If tileGridYOffset is not valid and fallback is null, 0 is returned.

**Parameters:**

fallback - the RenderedImage fallback.

**Returns:**

the appropriate value of tileGridYOffset.

---

### setTileGridYOffset

```
public ImageLayout setTileGridYOffset(int tileGridYOffset)
```

Sets tileGridYOffset to the supplied value and marks it as valid.

**Parameters:**

tileGridYOffset - the Y coordinate of tile (0, 0), as an int.

**Returns:**

a reference to this ImageLayout following the change.

---

### getTileWidth

```
public int getTileWidth(java.awt.image.RenderedImage fallback)
```

Returns the value of tileWidth if it is valid, and otherwise returns the value from the supplied RenderedImage. If tileWidth is not valid and fallback is null, 0 is returned.

**Parameters:**

fallback - the RenderedImage fallback.

**Returns:**

the appropriate value of tileWidth.

---

### setTileWidth

```
public ImageLayout setTileWidth(int tileWidth)
```

Sets tileWidth to the supplied value and marks it as valid.

**Parameters:**

tileWidth - the width of a tile, as an int.

**Returns:**

a reference to this ImageLayout following the change.

---

### getTileHeight

```
public int getTileHeight(java.awt.image.RenderedImage fallback)
```

Returns the value of tileHeight if it is valid, and otherwise returns the value from the supplied RenderedImage. If tileHeight is not valid and fallback is null, 0 is returned.

**Parameters:**

fallback - the RenderedImage fallback.

**Returns:**

the appropriate value of tileHeight.

---

### setTileHeight

```
public ImageLayout setTileHeight(int tileHeight)
```

Sets tileHeight to the supplied value and marks it as valid.

**Parameters:**

tileHeight - the height of a tile, as an int.

**Returns:**

a reference to this ImageLayout following the change.

---

## getSampleModel

```
public java.awt.image.SampleModel getSampleModel(java.awt.image.RenderedImage fallback)
```

Returns the value of sampleModel if it is valid, and otherwise returns the value from the supplied RenderedImage. If sampleModel is not valid and fallback is null, null is returned.

**Parameters:**

fallback - the RenderedImage fallback.

**Returns:**

the appropriate value of sampleModel.

---

## setSampleModel

```
public ImageLayout setSampleModel(java.awt.image.SampleModel sampleModel)
```

Sets sampleModel to the supplied value and marks it as valid.

**Parameters:**

sampleModel - the new SampleModel.

**Returns:**

a reference to this ImageLayout following the change.

---

## getColorModel

```
public java.awt.image.ColorModel getColorModel(java.awt.image.RenderedImage fallback)
```

Returns the value of colorModel if it is valid, and otherwise returns the value from the supplied RenderedImage. If colorModel is not valid and fallback is null, null is returned.

**Parameters:**

fallback - the RenderedImage fallback.

**Returns:**

the appropriate value of colorModel.

---

## setColorModel

```
public ImageLayout setColorModel(java.awt.image.ColorModel colorModel)
```

Sets colorModel to the supplied value and marks it as valid.

**Parameters:**

colorModel - the new ColorModel.

**Returns:**

a reference to this ImageLayout following the change.

---

## toString

```
public java.lang.String toString()
```

Returns a String containing the values of all valid fields.

**Overrides:**

toString in class java.lang.Object

---

## clone

```
public java.lang.Object clone()
```

Returns a clone of the ImageLayout as an Object.

**Overrides:**

clone in class java.lang.Object

---

## **writeObject**

```
private void writeObject(java.io.ObjectOutputStream out)
    throws java.io.IOException
```

Serialize the ImageLayout.

**Throws:**

java.io.IOException -

---

## **readObject**

```
private void readObject(java.io.ObjectInputStream in)
    throws java.io.IOException,
           java.lang.ClassNotFoundException
```

Deserialize the ImageLayout.

**Throws:**

java.io.IOException -

---

## javax.media.jai Class ImageMIPMap

java.lang.Object  
|  
+-- javax.media.jai.ImageMIPMap

**Direct Known Subclasses:**  
ImagePyramid

---

public class **ImageMIPMap**  
extends java.lang.Object  
implements ImageJAI

A class implementing the "MIP map" operation on a `RenderedImage`. Given a `RenderedImage`, which represents the image at the highest resolution level, the images at each lower resolution levels may be derived by performing a specific chain of operations to down sample the image at the next higher resolution level repeatedly. The highest resolution level is defined as level 0.

The `downSampler` is a chain of operations that is used to derive the image at the next lower resolution level from the image at the current resolution level. That is, given an image at resolution level *i*, the `downSampler` is used to obtain the image at resolution level *i*+1. The chain may contain one or more operation nodes; however, each node must be a `RenderedOp`. The parameter points to the last node in the chain. The very first node in the chain must be a `RenderedOp` that takes one `RenderedImage` as its source. All other nodes may have multiple sources. When traversing back up the chain, if a node has more than one source, the first source, `source0`, is used to move up the chain. This parameter is saved by reference.

**See Also:**  
`ImagePyramid`

---

### Field Detail

#### highestImage

protected java.awt.image.RenderedImage **highestImage**  
The image with the highest resolution.

---

#### currentImage

protected java.awt.image.RenderedImage **currentImage**  
The image at the current resolution level.

---

#### currentLevel

protected int **currentLevel**  
The current resolution level.

---

#### downSampler

protected RenderedOp **downSampler**  
The operation chain used to derive the lower resolution images.

---

### Constructor Detail

#### ImageMIPMap

protected **ImageMIPMap**()  
The default constructor.

---

## ImageMIPMap

```
public ImageMIPMap(java.awt.image.RenderedImage image,  
                  java.awt.geom.AffineTransform transform,  
                  Interpolation interpolation)
```

Constructor. The down sampler is an "affine" operation that uses the supplied AffineTransform and Interpolation objects. All input parameters are saved by reference.

**Parameters:**

image - The image with the highest resolution.  
transform - An affine matrix used with an "affine" operation to derive the lower resolution images.  
interpolation - The interpolation method for the "affine" operation. It may be null, in which case the default "nearest neighbor" interpolation method is used.

**Throws:**

java.lang.IllegalArgumentException - if image is null.  
java.lang.IllegalArgumentException - if transform is null.

---

## ImageMIPMap

```
public ImageMIPMap(java.awt.image.RenderedImage image,  
                  RenderedOp downSampler)
```

Constructor. The downSampler points to the last operation node in the RenderedOp chain. The very first operation in the chain must not have any source images specified; that is, its number of sources must be 0. All input parameters are saved by reference.

**Parameters:**

image - The image with the highest resolution.  
downSampler - The operation chain used to derive the lower resolution images. No validation is done on the first operation in the chain.

**Throws:**

NullPointerException - if image is null.  
NullPointerException - if downSampler is null.

---

## ImageMIPMap

```
public ImageMIPMap(RenderedOp downSampler)
```

Constructs a new ImageMIPMap from a RenderedOp chain. The downSampler points to the last operation node in the RenderedOp chain. The source image is determined by traversing up the chain; starting at the bottom node, given by the downSample parameter, we move to the first source of the node and repeat until we find either a sourceless RenderedOp or any other type of RenderedImage. The downSampler parameter is saved by reference and should not be modified during the lifetime of any ImageMIPMap referring to it.

**Parameters:**

downSampler - The operation chain used to derive the lower resolution images. The source of the first node in this chain is taken as the image with the highest resolution.

**Throws:**

NullPointerException - if downSampler is null.  
java.lang.IllegalArgumentException - if downSampler has no sources.  
java.lang.IllegalArgumentException - if an object other than a RenderedImage is found in the downSampler chain.

---

## Method Detail

### getPropertyNames

```
public java.lang.String[] getPropertyNames()
```

Returns an array of Strings recognized as names by this property source. If no property names match, null will be returned.

The default implementation returns null, i.e., no property names are recognized.

**Returns:**

An array of Strings giving the valid property names.

---

### getPropertyNames

```
public java.lang.String[] getPropertyNames(java.lang.String prefix)
```

Returns an array of Strings recognized as names by this property source that begin with the supplied prefix. If no property names are recognized, or no property names match, null will be returned. The comparison is done in a case-independent manner.

**Returns:**

An array of Strings giving the valid property names.

**Throws:**

NullPointerException - if prefix is null.

---

**getProperty**

```
public java.lang.Object getProperty(java.lang.String name)
```

Returns the specified property. The default implementation returns `java.awt.Image.UndefinedProperty`.

**Parameters:**

name - The name of the property.

**Returns:**

The value of the property, as an Object.

---

**getCurrentLevel**

```
public int getCurrentLevel()
```

Returns the current resolution level. The highest resolution level is defined as level 0.

---

**getCurrentImage**

```
public java.awt.image.RenderedImage getCurrentImage()
```

Returns the image at the current resolution level.

---

**getImage**

```
public java.awt.image.RenderedImage getImage(int level)
```

Returns the image at the specified resolution level. The requested level must be greater than or equal to 0 or null will be returned.

---

**getDownImage**

```
public java.awt.image.RenderedImage getDownImage()
```

Returns the image at the next lower resolution level, obtained by applying the `downSampler` on the image at the current resolution level.

---

**duplicate**

```
protected RenderedOp duplicate(RenderedOp op,  
                                java.util.Vector images)
```

Duplicates a `RenderedOp` chain. Each node in the chain must be a `RenderedOp`. The `op` parameter points to the last `RenderedOp` in the chain. The very first `op` in the chain must have no sources and its source will be set to the supplied image vector. When traversing up the chain, if any node has more than one source, the first source will be used. The first source of each node is duplicated; all other sources are copied by reference.

**Throws:**

NullPointerException - if `op` is null.

NullPointerException - if `images` is null.

---

**duplicate**

```
protected RenderedOp duplicate(RenderedOp op,  
                                java.awt.image.RenderedImage image)
```

Duplicates a `RenderedOp` chain. Each node in the chain must be a `RenderedOp`. The `op` parameter points to the last `RenderedOp` in the chain. The very first `op` in the chain must have no sources but should take 1 `RenderedImage` as its source and this source will be set to the supplied image. When traversing up the chain, if any node has more than one source, the first source will be used. The first source of each node is duplicated; all other sources are copied by reference.

**Throws:**

NullPointerException - if `op` is null.

NullPointerException - if `image` is null.

---

## duplicate

```
protected RenderedOp duplicate(RenderedOp op,  
                                java.awt.image.RenderedImage image0,  
                                java.awt.image.RenderedImage image1)
```

Duplicates a `RenderedOp` chain. Each node in the chain must be a `RenderedOp`. The `op` parameter points to the last `RenderedOp` in the chain. The very first `op` in the chain must have no sources but should take 2 `RenderedImages` as its sources and these sources will be set to the supplied images. When traversing up the chain, if any node has more than one source, the first source will be used. The first source of each node is duplicated; all other sources are copied by reference.

**Throws:**

- `NullPointerException` - if `op` is null.
- `NullPointerException` - if `image0` is null.
- `NullPointerException` - if `image1` is null.

---

## getAsRenderable

```
public java.awt.image.renderable.RenderableImage getAsRenderable(int numImages,  
                                                                float minX,  
                                                                float minY,  
                                                                float height)
```

Returns the current image as a `RenderableImage`. This method returns a `MultiResolutionRenderableImage`. The `numImages` parameter indicates the number of `RenderedImages` used to construct the `MultiResolutionRenderableImage`. Starting with the current image, the images are obtained by finding the necessary numbers of lower resolution images using the `downSampler`. The current level and current image will not be changed.

The `numImages` should be greater than or equal to 1. If a value of less than 1 is specified, this method uses 1 image, which is the current image.

**Throws:**

- `java.lang.IllegalArgumentException` - if `height` is less than 0.

**See Also:**

- `MultiResolutionRenderableImage`

---

## getAsRenderable

```
public java.awt.image.renderable.RenderableImage getAsRenderable()
```

Returns the current image as a `RenderableImage`. This method returns a `MultiResolutionRenderableImage` with the current image as the only source image, `minX` and `minY` set to 0.0, and `height` set to 1.0.

**See Also:**

- `MultiResolutionRenderableImage`

---

## javax.media.jai Class ImagePyramid

```
java.lang.Object
|
+-- javax.media.jai.ImageMIPMap
|
+-- javax.media.jai.ImagePyramid
```

---

public class **ImagePyramid**  
extends ImageMIPMap

A class implementing the "Pyramid" operation on a `RenderedImage`. Given a `RenderedImage` which represents the image at the highest resolution level, the images at lower resolution levels may be derived by performing a specific chain of operations to down sample the image at the higher resolution level repeatedly. Similarly, once an image at a lower resolution level is obtained, the images at higher resolution levels may be retrieved by performing a specific chain of operations to up sample the image at the lower resolution level repeatedly.

When an image is down sampled, the image at the higher resolution level is lost. However, the different image between the original image and the image obtained by up sampling the down sampled result image is saved. This different image, combined with the up sampling operations is used to retrieve the image at a higher resolution level from the image at a lower resolution level.

This is a bi-directional operation. A user may request an image at any resolution level greater than or equal to the highest resolution level, which is defined as level 0.

The `downSampler` is a chain of operations that is used to derive the image at the next lower resolution level from the image at the current resolution level. That is, given an image at resolution level `i`, `downSampler` is used to obtain the image at resolution level `i+1`. The chain may contain one or more operation nodes; however, each node must be a `RenderedOp`. The parameter points to the last node in the chain. The very first node in the chain must be a `RenderedOp` that takes one `RenderedImage` as its source. All other nodes may have multiple sources. When traversing back up the chain, if a node has more than one source, the first source, `source0`, is used to move up the chain. This parameter is saved by reference.

The `upSampler` is a chain of operations that is used to derive the image at the next higher resolution level from the image at the current resolution level. That is, given an image at resolution level `i`, `upSampler` is used to obtain the image at resolution level `i-1`. The requirement for this parameter is similar to that of the `downSampler` parameter.

The `differencer` is a chain of operations that is used to find the difference between an image at a particular resolution level and the image obtained by first down sampling that image then up sampling the result image of the down sampling operations. The chain may contain one or more operation nodes; however, each node must be a `RenderedOp`. The parameter points to the last node in the chain. The very first node in the chain must be a `RenderedOp` that takes two `RenderedImage`s as its sources. When traversing back up the chain, if a node has more than one source, the first source, `source0`, is used to move up the chain. This parameter is saved by reference.

The `combiner` is a chain of operations that is used to combine the result image of the up sampling operations and the different image saved to retrieve an image at a higher resolution level. The requirement for this parameter is similar to that of the `differencer` parameter.

**See Also:**  
`ImageMIPMap`

---

### Field Detail

#### **upSampler**

protected `RenderedOp` **upSampler**

The operation chain used to derive the higher resolution images.

---

#### **differencer**

protected `RenderedOp` **differencer**

The operation chain used to differ two images.

---

## combiner

protected RenderedOp **combiner**

The operation chain used to combine two images.

---

## diffImages

private java.util.Vector **diffImages**

The saved different images.

---

## Constructor Detail

### ImagePyramid

protected **ImagePyramid**()

The default constructor.

---

### ImagePyramid

```
public ImagePyramid(java.awt.image.RenderedImage image,
                    RenderedOp downSampler,
                    RenderedOp upSampler,
                    RenderedOp differencer,
                    RenderedOp combiner)
```

Constructor. The RenderedOp parameters point to the last operation node in each chain. The first operation in each chain must not have any source images specified; that is, its number of sources must be 0. All input parameters are saved by reference.

**Parameters:**

image - The image with the highest resolution.  
downSampler - The operation chain used to derive the lower resolution images.  
upSampler - The operation chain used to derive the higher resolution images.  
differencer - The operation chain used to differ two images.  
combiner - The operation chain used to combine two images.

**Throws:**

NullPointerException - if image is null.  
NullPointerException - if downSampler is null.  
NullPointerException - if upSampler is null.  
NullPointerException - if differencer is null.  
NullPointerException - if combiner is null.

---

### ImagePyramid

```
public ImagePyramid(RenderedOp downSampler,
                    RenderedOp upSampler,
                    RenderedOp differencer,
                    RenderedOp combiner)
```

Constructor. The RenderedOp parameters point to the last operation node in each chain. The first operation in the downSampler chain must have the image with the highest resolution as its source. The first operation in all other chains must not have any source images specified; that is, its number of sources must be 0. All input parameters are saved by reference.

**Parameters:**

downSampler - The operation chain used to derive the lower resolution images.  
upSampler - The operation chain used to derive the higher resolution images.  
differencer - The operation chain used to differ two images.  
combiner - The operation chain used to combine two images.

**Throws:**

NullPointerException - if downSampler is null.  
NullPointerException - if upSampler is null.  
NullPointerException - if differencer is null.  
NullPointerException - if combiner is null.  
java.lang.IllegalArgumentException - if downSampler has no sources.  
java.lang.IllegalArgumentException - if an object other than a RenderedImage is found in the downSampler chain.

## Method Detail

### **getImage**

public java.awt.image.RenderedImage **getImage**(int level)

Returns the image at the specified resolution level. The requested level must be greater than or equal to 0 or null will be returned. The image is obtained by either down sampling or up sampling the current image.

**Overrides:**

getImage in class ImageMIPMap

---

### **getDownImage**

public java.awt.image.RenderedImage **getDownImage**()

Returns the image at the next lower resolution level, obtained by applying the downSampler on the image at the current resolution level.

**Overrides:**

getDownImage in class ImageMIPMap

---

### **getUpImage**

public java.awt.image.RenderedImage **getUpImage**()

Returns the image at the previous higher resolution level, If the current image is already at level 0, then the current image will be returned without further up sampling.

The image is obtained by first up sampling the current image, then combine the result image with the previously saved different image using the combiner op chain.

---

### **getDiffImage**

public java.awt.image.RenderedImage **getDiffImage**()

Returns the difference image between the current image and the image obtained by first down sampling the current image then up sampling the result image of down sampling. This is done using the differencer op chain. The current level and current image will not be changed.

---

## javax.media.jai Class ImageSequence

```
java.lang.Object
|
+-- javax.media.jai.CollectionImage
|
+-- javax.media.jai.ImageSequence
```

---

public class **ImageSequence**  
extends `CollectionImage`

A class representing a sequence of images, each associated with a time stamp and a camera position. The images are of the type `javax.media.jai.PlanarImage`; the time stamps are of the type `float`; the camera positions are of the type `java.lang.Object`. The tuple (image, time stamp, camera position) is represented by class `javax.media.jai.SequentialImage`.

This class can be used to represent video or time-lapse photography.

### See Also:

`PlanarImage`, `SequentialImage`

---

## Constructor Detail

### ImageSequence

protected **ImageSequence**()

The default constructor.

---

### ImageSequence

public **ImageSequence**(java.util.Collection images)

Constructs a class that represents a sequence of images.

#### Parameters:

images - A collection of `SequentialImage`.

#### Throws:

`NullPointerException` - if images is null.

---

## Method Detail

### getImage

public `PlanarImage` **getImage**(float ts)

Returns the image associated with the specified time stamp, or null if no match is found.

---

### getImage

public `PlanarImage` **getImage**(java.lang.Object cp)

Returns the image associated with the specified camera position, or null if cp is null or if no match is found.

---

### getTimeStamp

public float **getTimeStamp**(`PlanarImage` pi)

Returns the time stamp associated with the specified image, or `-Float.MAX_VALUE` if pi is null or if no match is found.

---

### getCameraPosition

public java.lang.Object **getCameraPosition**(`PlanarImage` pi)

Returns the camera position associated with the specified image, or null if pi is null or if no match is found.

---

## **add**

public boolean **add**(java.lang.Object o)

Adds a SequentialImage to this collection. If the specified image is null, it is not added to the collection.

**Returns:**

true if and only if the SequentialImage is added to the collection.

**Overrides:**

add in class CollectionImage

---

## **remove**

public boolean **remove**(PlanarImage pi)

Removes the SequentialImage that contains the specified image from this collection.

**Returns:**

true if and only if a SequentialImage with the specified image is removed from the collection.

---

## **remove**

public boolean **remove**(float ts)

Removes the SequentialImage that contains the specified time stamp from this collection.

**Returns:**

true if and only if a SequentialImage with the specified time stamp is removed from the collection.

---

## **remove**

public boolean **remove**(java.lang.Object cp)

Removes the SequentialImage that contains the specified camera position from this collection.

**Returns:**

true if and only if a SequentialImage with the specified camera position is removed from the collection.

**Overrides:**

remove in class CollectionImage

---

## javax.media.jai Class ImageStack

```
java.lang.Object
|
+-- javax.media.jai.CollectionImage
|
+-- javax.media.jai.ImageStack
```

---

public abstract class **ImageStack**  
extends `CollectionImage`

A class representing a stack of images, each associated with a spatial orientation defined in a common coordinate system. The images are of the type `javax.media.jai.PlanarImage`; the coordinates are of the type `java.lang.Object`. The tuple (image, coordinate) is represented by class `javax.media.jai.CoordinateImage`.

This class can be used to represent medical or geophysical images.

### See Also:

`PlanarImage`

---

## Constructor Detail

### ImageStack

protected **ImageStack**()  
The default constructor.

---

### ImageStack

public **ImageStack**(java.util.Collection images)  
Constructor.  
**Parameters:**  
images - A collection of `CoordinateImage`.  
**Throws:**  
`NullPointerException` - if images is null.

---

## Method Detail

### getImage

public `PlanarImage` **getImage**(java.lang.Object c)  
Returns the image associated with the specified coordinate, or null if c is null or if no match is found.

---

### getCoordinate

public java.lang.Object **getCoordinate**(`PlanarImage` pi)  
Returns the coordinate associated with the specified image, or null if pi is null or if no match is found.

---

### add

public boolean **add**(java.lang.Object o)  
Adds a `CoordinateImage` to this collection. If the specified image is null, it is not added to the collection.  
**Returns:**  
true if and only if the `CoordinateImage` is added to the collection.  
**Overrides:**  
add in class `CollectionImage`

---

**remove**

public boolean **remove**(PlanarImage pi)

Removes the CoordinateImage that contains the specified image from this collection.

**Returns:**

true if and only if a CoordinateImage containing the specified image is removed from the collection.

---

**remove**

public boolean **remove**(java.lang.Object c)

Removes the CoordinateImage that contains the specified coordinate from this collection.

**Returns:**

true if and only if a CoordinateImage containing the specified coordinate is removed from the collection.

**Overrides:**

remove in class CollectionImage

---

## javax.media.jai Class IntegerSequence

java.lang.Object  
|  
+-- javax.media.jai.IntegerSequence

---

public class **IntegerSequence**  
extends java.lang.Object

A growable sorted integer set. Adding an integer to the sequence results in it being placed into the sequence in sorted order. Adding an integer that is already part of the sequence has no effect.

This structure is used by various subclasses of OpImage to keep track of horizontal and vertical source splits. Each instance of IntegerSequence provides an internal enumeration by means of which the elements of the sequence may be accessed in order. The enumerator is initialized by the `startEnumeration` method, and the `hasMoreElements` and `nextElement` methods allow looping through the elements. Only one enumeration at a time is supported. Calling `insert()` from multiple threads is not supported.

---

### Field Detail

#### **min**

private int **min**  
Lower bound of the valid integer range.

---

#### **max**

private int **max**  
Upper bound of the valid integer range.

---

#### **DEFAULT\_CAPACITY**

private static final int **DEFAULT\_CAPACITY**  
The default initial capacity of iArray.

---

#### **iArray**

private int[] **iArray**  
The array storing the unsorted integer values.

---

#### **capacity**

private int **capacity**  
The capacity of iArray.

---

#### **numElts**

private int **numElts**  
The number of (non-unique) elements actually stored in iArray.

---

#### **isSorted**

private boolean **isSorted**  
True if iArray has been sorted and purged of duplicates.

---

## currentIndex

private int **currentIndex**

The current element of the iteration.

## Constructor Detail

### IntegerSequence

public **IntegerSequence**(int min,  
int max)

Constructs a sequence bounded by an inclusive range of values.

### IntegerSequence

public **IntegerSequence**()

Constructs a sequence that may contain any integer value.

## Method Detail

### insert

public void **insert**(int element)

Inserts an integer into the sequence. If the value falls out of the desired range, it will be silently rejected. Inserting an element that is already a member of the sequence has no effect.

**Parameters:**

element - The int to be inserted.

### startEnumeration

public void **startEnumeration**()

Resets the iterator to the beginning of the sequence.

### hasMoreElements

public boolean **hasMoreElements**()

Returns true if more elements are available to be iterated over.

### nextElement

public int **nextElement**()

Returns the next element of the iteration in ascending order. If the end of the array has been reached, a `java.util.NoSuchElementException` will be thrown.

**Throws:**

`java.util.NoSuchElementException` - if the end of the array has been reached.

### getNumElements

public int **getNumElements**()

Returns the number of elements contained within this `IntegerSequence`.

### toString

public java.lang.String **toString**()

Returns a String representation of the sequence for debugging.

**Overrides:**

`toString` in class `java.lang.Object`

---

## javax.media.jai Class Interpolation

java.lang.Object

└-- javax.media.jai.Interpolation

### Direct Known Subclasses:

InterpolationBilinear, InterpolationNearest, InterpolationTable

---

public abstract class **Interpolation**

extends java.lang.Object

implements java.io.Serializable

An object encapsulating a particular algorithm for image interpolation (resampling). An Interpolation captures the notion of performing sampling on a regular grid of pixels using a local neighborhood. It is intended to be used by operations that resample their sources, including affine mapping and warping.

Resampling is the action of computing a pixel value at a possibly non-integral position of an image. The image defines pixel values at integer lattice points, and it is up to the resampler to produce a reasonable value for positions not falling on the lattice. A number of techniques are used in practice, the most common being nearest-neighbor, which simply takes the value of the closest lattice point; bilinear, which interpolates linearly between the four closest lattice points; and bicubic, which applies a piecewise polynomial function to a 4x4 neighborhood of nearby points. The area over which a resampling function needs to be computed is referred to as its support; thus the standard resampling functions have supports of 1, 4, and 16 pixels respectively.

Mathematically, the ideal resampling function for a band-limited image (one containing no energy above a given frequency) is the sinc function, equal to  $\sin(x)/x$ . This has practical limitations, in particular its infinite support, which lead to the use of the standard approximations described above.

Other interpolation functions may be required to solve problems other than the resampling of band-limited image data. When shrinking an image, it is common to use a function that combines area averaging with resampling in order to remove undesirable high frequencies as part of the interpolation process. Other application areas may use interpolating functions that operate under other assumptions about image data, such as taking the maximum value of a 2x2 neighborhood. The interpolation class provides a framework in which a variety of interpolation schemes may be expressed.

Many interpolations are separable, that is, they may be equivalently rewritten as a horizontal interpolation followed by a vertical one (or vice versa). In practice, some precision may be lost by the rounding and truncation that takes place between the passes. The Interpolation class assumes separability and implements all vertical interpolation methods in terms of corresponding horizontal methods, and defines `isSeparable()` to return true. A subclass may override these methods to provide distinct implementations of horizontal and vertical interpolation. Some subclasses may implement the two-dimensional interpolation methods directly, yielding more precise results, while others may implement these using a two-pass approach.

A minimal Interpolation subclass must call the Interpolation constructor (`super()`) and then set at least the following fields.

```
leftPadding
rightPadding
topPadding
bottomPadding
width
height
subsampleBitsH
subsampleBitsV
```

It must also implement at least the following methods.

```
int interpolateH(int[] samples, int xfrac)
float interpolateH(float[] samples, float xfrac)
double interpolateH(double[] samples, float xfrac)
```

All other methods are defined in terms of these methods for ease of implementation of new Interpolation subclasses.

Since interpolation is generally performed for every pixel of a destination image, efficiency is important. In particular, passing source samples by means of arrays is likely to be unacceptably slow. Accordingly, methods are provided for the common cases of 2x1, 1x2, 4x1, 1x4, 2x2, and 4x4 input grids. These methods are defined in the superclass to package their arguments into arrays and forward the call to the array versions, in order to simplify implementation. They should be called only on Interpolation objects with the correct width and height. In other words, an implementor of an InterpolationSubclass may implement "`interpolateH(int s0, int s1, int xfrac)`" assuming that the interpolation width is in fact equal to 2, and does not need to enforce this constraint.

The fractional position of interpolation (`xfrac`, `yfrac`) is always between 0.0 and 1.0 (not including 1.0). For integral image data, the fraction is represented as a scaled integer between 0 and  $2^n - 1$ , where  $n$  is a small integer. The value of  $n$  in the horizontal and vertical directions may be obtained by calling `getSubsampleBitsH()` and `getSubsampleBitsV()`. In general, code that makes use of an externally-provided Interpolation object must query that object to determine its desired positional precision.

For float and double images, a float between 0.0F and 1.0F (not including 1.0F) is used as a positional specifier in the interest of greater accuracy.

It is important to understand that the subsampleBits precision is used only to indicate the scaling implicit in the fractional locations and then only with integral image data types. An implementation is not required to actually quantize its interpolation coefficients to match the specified subsampling precision.

The diagrams below illustrate the pixels involved in one-dimensional interpolation. Point s0 is the interpolation kernel key position.

The diagram below illustrates the pixels involved in two-dimensional interpolation. Point s00 is the interpolation kernel key position.

The subclasses of Interpolation include InterpolationNearest, InterpolationBilinear, InterpolationBicubic, and InterpolationBicubic2 (a variant defined by a different polynomial function). These subclasses are marked 'final,' so users may identify them by name (using 'instanceof') and write specialized code for them. This may also allow inlining to occur on some virtual machines. These classes do provide correct, if less than optimal code for performing their interpolations, so it is possible to use any Interpolation object in a generic manner. The Sun-provided InterpolationBilinear and InterpolationBicubic classes provide a more optimal implementation while using the same semantics.

The InterpolationTable class is a subclass of Interpolation that divides the set of subsample positions into a fixed number of "bins" and stores a kernel for each bin. InterpolationBicubic and InterpolationBicubic2 are implemented in terms of InterpolationTable since a direct implementation is very expensive.

Field Detail

INTERP\_NEAREST

public static final int INTERP\_NEAREST

A constant specifying interpolation by the InterpolationNearest class.

INTERP\_BILINEAR

public static final int INTERP\_BILINEAR

A constant specifying interpolation by the InterpolationBilinear class.

## **INTERP\_BICUBIC**

public static final int **INTERP\_BICUBIC**

A constant specifying interpolation by the InterpolationBicubic class.

---

## **INTERP\_BICUBIC\_2**

public static final int **INTERP\_BICUBIC\_2**

A constant specifying interpolation by the InterpolationBicubic2 class.

---

## **nearestInstance**

private static final Interpolation **nearestInstance**

---

## **bilinearInstance**

private static final Interpolation **bilinearInstance**

---

## **bicubicInstance**

private static final Interpolation **bicubicInstance**

---

## **bicubic2Instance**

private static final Interpolation **bicubic2Instance**

---

## **leftPadding**

protected int **leftPadding**

The number of pixels lying to the left of the interpolation kernel key position.

---

## **rightPadding**

protected int **rightPadding**

The number of pixels lying to the right of the interpolation kernel key position.

---

## **topPadding**

protected int **topPadding**

The number of pixels lying above the interpolation kernel key position.

---

## **bottomPadding**

protected int **bottomPadding**

The number of pixels lying below the interpolation kernel key position.

---

## **subsampleBitsH**

protected int **subsampleBitsH**

The numbers of bits used for the horizontal subsample position. This value determines how integer fractional positions are to be interpreted.

---

## **subsampleBitsV**

protected int **subsampleBitsV**

The numbers of bits used for the vertical subsample position. This value determines how integer fractional positions are to be interpreted.

---

## width

protected int **width**

The width of the interpolation kernel in pixels.

---

## height

protected int **height**

The height of the interpolation kernel in pixels.

---

## Constructor Detail

### Interpolation

public **Interpolation**()

Construct Interpolation object with no fields set. This constructor should only be invoked by subclasses which will subsequently set all fields themselves.

---

### Interpolation

```
public Interpolation(int width,
                     int height,
                     int leftPadding,
                     int rightPadding,
                     int topPadding,
                     int bottomPadding,
                     int subsampleBitsH,
                     int subsampleBitsV)
```

Construct interpolation object with all parameters set. Subclasses must supply all parameters.

---

## Method Detail

### getInstance

public static Interpolation **getInstance**(int type)

Creates an interpolation of one of the standard types. This is intended strictly as a convenience method.

**Parameters:**

type - one of: INTERP\_NEAREST, INTERP\_BILINEAR, INTERP\_BICUBIC, or INTERP\_BICUBIC\_2

**Returns:**

an appropriate Interpolation object.

**Throws:**

java.lang.IllegalArgumentException - if an unrecognized type is supplied.

---

### getLeftPadding

public int **getLeftPadding**()

Returns the number of samples required to the left of the center.

---

### getRightPadding

public int **getRightPadding**()

Returns the number of samples required to the right of the center.

---

### getTopPadding

public int **getTopPadding**()

Returns the number of samples required above the center.

---

## getBottomPadding

```
public int getBottomPadding()
```

Returns the number of samples required below the center.

---

## getWidth

```
public int getWidth()
```

Returns the number of samples required for horizontal resampling.

---

## getHeight

```
public int getHeight()
```

Returns the number of samples required for vertical resampling.

---

## isSeparable

```
public boolean isSeparable()
```

Returns true if the interpolation can be performed in a separable manner, that is, by performing a separate pass in each dimension. It is the caller's responsibility to deal with issues of precision. By default, true is returned.

---

## getSubsampleBitsH

```
public int getSubsampleBitsH()
```

Returns the number of bits used to index subsample positions in the horizontal direction. All integral 'xfrac' parameters should range between 0 and  $2^{(\text{getSubsampleBitsH}() - 1)}$ .

In general, the caller is responsible for determining the number of subsample bits of any Interpolation object it receives and setting up its position variables accordingly. Some Interpolation objects allow the number of bits to be set at construction time.

---

## getSubsampleBitsV

```
public int getSubsampleBitsV()
```

Returns the number of bits used to index subsample positions in the vertical direction. All integral 'yfrac' parameters should range between 0 and  $2^{(\text{getSubsampleBitsV}() - 1)}$ .

---

## interpolateH

```
public abstract int interpolateH(int[] samples,  
                                int xfrac)
```

Performs horizontal interpolation on a 1-dimensional array of integral samples.

An implementation is not required to actually quantize its interpolation coefficients to match the specified subsampling precision. However, the supplied value of xfrac (or yfrac) must match the precision of its corresponding subsampleBits. For example, with a subsampleBitsH value of 8, xfrac must lie between 0 and 255.

**Parameters:**

`samples` - an array of ints.

`xfrac` - the subsample position, multiplied by  $2^{(\text{subsampleBitsH})}$ .

**Returns:**

the interpolated value as an int.

---

## interpolateV

```
public int interpolateV(int[] samples,  
                       int yfrac)
```

Performs vertical interpolation on a 1-dimensional array of integral samples.

By default, vertical interpolation is defined to be the same as horizontal interpolation. Subclasses may choose to implement them differently.

**Parameters:**

`samples` - an array of ints.

`yfrac` - the Y subsample position, multiplied by  $2^{(\text{subsampleBitsV})}$ .

**Returns:**  
the interpolated value as an int.  
**See Also:**  
`interpolateH(int[], int)`

---

## interpolate

```
public int interpolate(int[][] samples,  
                       int xfrac,  
                       int yfrac)
```

Performs interpolation on a 2-dimensional array of integral samples. By default, this is implemented using a two-pass approach.

**Parameters:**  
`samples` - a two-dimensional array of ints.  
`xfrac` - the X subsample position, multiplied by  $2^{(\text{subsampleBitsH})}$ .  
`yfrac` - the Y subsample position, multiplied by  $2^{(\text{subsampleBitsV})}$ .

**Returns:**  
the interpolated value as an int.

**See Also:**  
`interpolateH(int[], int)`

---

## interpolateH

```
public int interpolateH(int s0,  
                        int s1,  
                        int xfrac)
```

Performs horizontal interpolation on a pair of integral samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if `width == 2` and `leftPadding == 0`.

**Parameters:**  
`s0` - the central sample.  
`s1` - the sample to the right of the central sample.  
`xfrac` - the subsample position, multiplied by  $2^{(\text{subsampleBitsH})}$ .

**Returns:**  
the interpolated value as an int.

**See Also:**  
`interpolateH(int[], int)`

---

## interpolateH

```
public int interpolateH(int s_  
                        int s0,  
                        int s1,  
                        int s2,  
                        int xfrac)
```

Performs horizontal interpolation on a quadruple of integral samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if `width == 4` and `leftPadding == 1`.

**Parameters:**  
`s_` - the sample to the left of the central sample.  
`s0` - the central sample.  
`s1` - the sample to the right of the central sample.  
`s2` - the sample to the right of `s1`.  
`xfrac` - the subsample position, multiplied by  $2^{(\text{subsampleBitsH})}$ .

**Returns:**  
the interpolated value as an int.

**See Also:**  
`interpolateH(int[], int)`

---

## interpolateV

```
public int interpolateV(int s0,  
                        int s1,  
                        int yfrac)
```

Performs vertical interpolation on a pair of integral samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if height == 2 and topPadding == 0.

By default, vertical interpolation is identical to horizontal interpolation. Subclasses may choose to implement them differently.

**Parameters:**

s0 - the central sample.  
s1 - the sample below the central sample.  
yfrac - the Y subsample position, multiplied by  $2^{(\text{subsampleBitsV})}$ .

**Returns:**

the interpolated value as an int.

**See Also:**

interpolateH(int[], int)

---

## interpolateV

```
public int interpolateV(int s_  
                        int s0,  
                        int s1,  
                        int s2,  
                        int yfrac)
```

Performs vertical interpolation on a quadruple of integral samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if height == 4 and topPadding == 1.

By default, vertical interpolation is identical to horizontal interpolation. Subclasses may choose to implement them differently.

**Parameters:**

s\_ - the sample above the central sample.  
s0 - the central sample.  
s1 - the sample below the central sample.  
s2 - the sample below s1.  
yfrac - the Y subsample position, multiplied by  $2^{(\text{subsampleBitsV})}$ .

**Returns:**

the interpolated value as an int.

**See Also:**

interpolateH(int[], int)

---

## interpolate

```
public int interpolate(int s00,  
                      int s01,  
                      int s10,  
                      int s11,  
                      int xfrac,  
                      int yfrac)
```

Performs interpolation on a 2x2 grid of integral samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if width == height == 2 and leftPadding == topPadding == 0.

**Parameters:**

s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and to the right of the central sample.  
xfrac - the X subsample position, multiplied by  $2^{(\text{subsampleBitsH})}$ .  
yfrac - the Y subsample position, multiplied by  $2^{(\text{subsampleBitsV})}$ .

**Returns:**

the interpolated value as an int.

**See Also:**

interpolateH(int[], int)

---

## interpolate

```
public int interpolate(int s__,
                      int s_0,
                      int s_1,
                      int s_2,
                      int s0_,
                      int s00,
                      int s01,
                      int s02,
                      int s1_,
                      int s10,
                      int s11,
                      int s12,
                      int s2_,
                      int s20,
                      int s21,
                      int s22,
                      int xfrac,
                      int yfrac)
```

Performs interpolation on a 4x4 grid of integral samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if width == height == 4 and leftPadding == topPadding == 1.

### Parameters:

s\_\_ - the sample above and to the left of the central sample.  
s\_0 - the sample above the central sample.  
s\_1 - the sample above and one to the right of the central sample.  
s\_2 - the sample above and two to the right of the central sample.  
s0\_ - the sample to the left of the central sample.  
s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s02 - the sample two to the right of the central sample.  
s1\_ - the sample below and one to the left of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and one to the right of the central sample.  
s12 - the sample below and two to the right of the central sample.  
s2\_ - the sample two below and one to the left of the central sample.  
s20 - the sample two below the central sample.  
s21 - the sample two below and one to the right of the central sample.  
s22 - the sample two below and two to the right of the central sample.  
xfrac - the X subsample position, multiplied by  $2^{(\text{subsampleBitsH})}$ .  
yfrac - the Y subsample position, multiplied by  $2^{(\text{subsampleBitsV})}$ .

### Returns:

the interpolated value as an int.

### See Also:

interpolateH(int[], int)

---

## interpolateH

```
public abstract float interpolateH(float[] samples,
                                  float xfrac)
```

Performs horizontal interpolation on a 1-dimensional array of floating-point samples representing a row of samples. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

### Parameters:

samples - an array of floats.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).

### Returns:

the interpolated value as a float.

---

## interpolateV

```
public float interpolateV(float[] samples,
                          float yfrac)
```

Performs vertical interpolation on a 1-dimensional array of floating-point samples representing a column of samples. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

By default, vertical interpolation is identical to horizontal interpolation. Subclasses may choose to implement them differently.

**Parameters:**

`samples` - an array of floats.  
`yfrac` - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

---

## interpolate

```
public float interpolate(float[][] samples,  
                        float xfrac,  
                        float yfrac)
```

Performs interpolation on a 2-dimensional array of floating-point samples. By default, this is implemented using a two-pass approach. The setting of `subsampleBits` need not have any effect on the interpolation accuracy of an implementation of this method.

**Parameters:**

`samples` - an array of floats.  
`xfrac` - the X subsample position, in the range [0.0F, 1.0F).  
`yfrac` - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

---

## interpolateH

```
public float interpolateH(float s0,  
                        float s1,  
                        float xfrac)
```

Performs horizontal interpolation on a pair of floating-point samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if `width == 2` and `leftPadding == 0`. The setting of `subsampleBits` need not have any effect on the interpolation accuracy of an implementation of this method.

**Parameters:**

`s0` - the central sample.  
`s1` - the sample to the right of the central sample.  
`xfrac` - the subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

---

## interpolateH

```
public float interpolateH(float s_  
                        float s0,  
                        float s1,  
                        float s2,  
                        float xfrac)
```

Performs horizontal interpolation on a quadruple of floating-point samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if `width == 4` and `leftPadding == 1`. The setting of `subsampleBits` need not have any effect on the interpolation accuracy of an implementation of this method.

**Parameters:**

`s_` - the sample to the left of the central sample.  
`s0` - the central sample.  
`s1` - the sample to the right of the central sample.  
`s2` - the sample to the right of `s1`.  
`xfrac` - the subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

---

## interpolateV

```
public float interpolateV(float s0,  
                        float s1,  
                        float yfrac)
```

Performs vertical interpolation on a pair of floating-point samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if height == 2 and topPadding == 0. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

By default, vertical interpolation is identical to horizontal interpolation. Subclasses may choose to implement them differently.

**Parameters:**

s0 - the central sample.  
s1 - the sample below the central sample.  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

---

## interpolateV

```
public float interpolateV(float s_,
                        float s0,
                        float s1,
                        float s2,
                        float yfrac)
```

Performs vertical interpolation on a quadruple of floating-point samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if height == 4 and topPadding == 1. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

By default, vertical interpolation is identical to horizontal interpolation. Subclasses may choose to implement them differently.

**Parameters:**

s\_ - the sample above the central sample.  
s0 - the central sample.  
s1 - the sample below the central sample.  
s2 - the sample below s1.  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

---

## interpolate

```
public float interpolate(float s00,
                        float s01,
                        float s10,
                        float s11,
                        float xfrac,
                        float yfrac)
```

Performs interpolation on a 2x2 grid of floating-point samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if width == height == 2 and leftPadding == topPadding == 0. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

**Parameters:**

s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and to the right of the central sample.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

---

## interpolate

```
public float interpolate(float s__,
                        float s_0,
                        float s_1,
                        float s_2,
                        float s0_,
                        float s00,
                        float s01,
                        float s02,
                        float s1_,
```

```

float s10,
float s11,
float s12,
float s2_,
float s20,
float s21,
float s22,
float xfrac,
float yfrac)

```

Performs interpolation on a 4x4 grid of floating-point samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if width == height == 4 and leftPadding == topPadding == 1. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

**Parameters:**

s\_\_ - the sample above and to the left of the central sample.  
s\_0 - the sample above the central sample.  
s\_1 - the sample above and one to the right of the central sample.  
s\_2 - the sample above and two to the right of the central sample.  
s0\_ - the sample to the left of the central sample.  
s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s02 - the sample two to the right of the central sample.  
s1\_ - the sample below and one to the left of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and one to the right of the central sample.  
s12 - the sample below and two to the right of the central sample.  
s2\_ - the sample two below and one to the left of the central sample.  
s20 - the sample two below the central sample.  
s21 - the sample two below and one to the right of the central sample.  
s22 - the sample two below and two to the right of the central sample.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

---

## interpolateH

```

public abstract double interpolateH(double[] samples,
float xfrac)

```

Performs horizontal interpolation on a 1-dimensional array of double samples representing a row of samples. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

**Parameters:**

samples - an array of doubles.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

---

## interpolateV

```

public double interpolateV(double[] samples,
float yfrac)

```

Performs vertical interpolation on a 1-dimensional array of double samples representing a column of samples. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

By default, vertical interpolation is identical to horizontal interpolation. Subclasses may choose to implement them differently.

**Parameters:**

samples - an array of doubles.  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

---

## interpolate

```
public double interpolate(double[][] samples,  
                           float xfrac,  
                           float yfrac)
```

Performs interpolation on a 2-dimensional array of double samples. By default, this is implemented using a two-pass approach. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

**Parameters:**

samples - an array of doubles.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

---

## interpolateH

```
public double interpolateH(double s0,  
                           double s1,  
                           float xfrac)
```

Performs horizontal interpolation on a pair of double samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if width == 2 and leftPadding == 0. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

**Parameters:**

s0 - the central sample.  
s1 - the sample to the right of the central sample.  
xfrac - the subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

---

## interpolateH

```
public double interpolateH(double s_  
                           double s0,  
                           double s1,  
                           double s2,  
                           float xfrac)
```

Performs horizontal interpolation on a quadruple of double samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if width == 4 and leftPadding == 1. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

**Parameters:**

s\_ - the sample to the left of the central sample.  
s0 - the central sample.  
s1 - the sample to the right of the central sample.  
s2 - the sample to the right of s1.  
xfrac - the subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

---

## interpolateV

```
public double interpolateV(double s0,  
                           double s1,  
                           float yfrac)
```

Performs vertical interpolation on a pair of double samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if height == 2 and topPadding == 0. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

By default, vertical interpolation is identical to horizontal interpolation. Subclasses may choose to implement them differently.

**Parameters:**

s0 - the central sample.  
s1 - the sample below the central sample.  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**  
the interpolated value as a double.

---

## interpolateV

```
public double interpolateV(double s_,  
                           double s0,  
                           double s1,  
                           double s2,  
                           float yfrac)
```

Performs vertical interpolation on a quadruple of double samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if height == 4 and topPadding == 1. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

By default, vertical interpolation is identical to horizontal interpolation. Subclasses may choose to implement them differently.

**Parameters:**

s\_ - the sample above the central sample.  
s0 - the central sample.  
s1 - the sample below the central sample.  
s2 - the sample below s1.  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**  
the interpolated value as a double.

---

## interpolate

```
public double interpolate(double s00,  
                          double s01,  
                          double s10,  
                          double s11,  
                          float xfrac,  
                          float yfrac)
```

Performs interpolation on a 2x2 grid of double samples. Subclasses may implement this method to provide a speed improvement over the array method. This base class method merely calls the array method. It should only be called if width == height == 2 and leftPadding == topPadding == 0. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

**Parameters:**

s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and to the right of the central sample.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**  
the interpolated value as a double.

---

## interpolate

```
public double interpolate(double s__,  
                          double s_0,  
                          double s_1,  
                          double s_2,  
                          double s0_,  
                          double s00,  
                          double s01,  
                          double s02,  
                          double s1_,  
                          double s10,  
                          double s11,  
                          double s12,  
                          double s2_,  
                          double s20,  
                          double s21,  
                          double s22,  
                          float xfrac,  
                          float yfrac)
```

Performs interpolation on a 4x4 grid of double samples. It should only be called if width == height == 4 and leftPadding == topPadding == 1. The setting of subsampleBits need not have any effect on the interpolation accuracy of an implementation of this method.

**Parameters:**

- s\_\_ - the sample above and to the left of the central sample.
- s\_0 - the sample above the central sample.
- s\_1 - the sample above and one to the right of the central sample.
- s\_2 - the sample above and two to the right of the central sample.
- s0\_ - the sample to the left of the central sample.
- s00 - the central sample.
- s01 - the sample to the right of the central sample.
- s02 - the sample two to the right of the central sample.
- s1\_ - the sample below and one to the left of the central sample.
- s10 - the sample below the central sample.
- s11 - the sample below and one to the right of the central sample.
- s12 - the sample below and two to the right of the central sample.
- s2\_ - the sample two below and one to the left of the central sample.
- s20 - the sample two below the central sample.
- s21 - the sample two below and one to the right of the central sample.
- s22 - the sample two below and two to the right of the central sample.
- xfrac - the X subsample position, in the range [0.0F, 1.0F).
- yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

---

## javax.media.jai Class InterpolationBicubic

```
java.lang.Object
|
+--javax.media.jai.Interpolation
|   |
|   +--javax.media.jai.InterpolationTable
|       |
|       +--javax.media.jai.InterpolationBicubic
```

---

public final class **InterpolationBicubic**  
extends InterpolationTable

A class representing bicubic interpolation.

InterpolationBicubic is a subclass of Interpolation that performs interpolation using the piecewise cubic polynomial:

$$\begin{aligned} r(x) &= (a + 2)|x|^3 - (a + 3)|x|^2 + 1, & 0 \leq |x| < 1 \\ r(x) &= a|x|^3 - 5a|x|^2 + 8a|x| - 4a, & 1 \leq |x| < 2 \\ r(x) &= 0, & \text{otherwise} \end{aligned}$$

with 'a' set to -0.5.

A neighborhood extending one sample to the left of and above the central sample, and two samples to the right of and below the central sample is required to perform bicubic interpolation.

This implementation creates an InterpolationTable whose integer coefficients have eight bits of precision to the right of the binary point.

The diagrams below illustrate the pixels involved in one-dimensional interpolation.

The diagram below illustrates the pixels involved in two-dimensional interpolation.

The class is marked 'final' so that it may be more easily inlined.

## Constructor Detail

### InterpolationBicubic

```
public InterpolationBicubic(int subsampleBits)
```

Constructs an InterpolationBicubic with a given subsample precision, in bits. This precision is applied to both axes.

This implementation creates an InterpolationTable whose integer coefficients have eight bits of precision to the right of the binary point.

**Parameters:**

subsampleBits - the subsample precision.

## Method Detail

### dataHelper

```
private static float[] dataHelper(int subsampleBits)
```

---

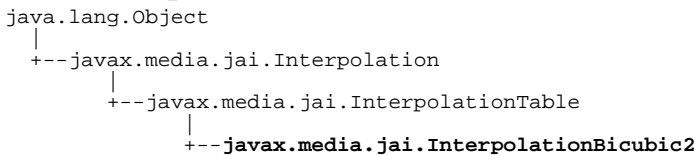

### bicubic

```
private static float bicubic(float x)
```

Returns the bicubic polynomial value at a certain value of x.

---

**javax.media.jai**  
**Class InterpolationBicubic2**

public final class **InterpolationBicubic2**  
extends InterpolationTable

A class representing bicubic interpolation using a different polynomial than InterpolationBicubic.

InterpolationBicubic2 is a subclass of Interpolation that performs interpolation using the piecewise cubic polynomial:

$$\begin{aligned} r(x) &= (a + 2)|x|^3 - (a + 3)|x|^2 + 1, & 0 \leq |x| < 1 \\ r(x) &= a|x|^3 - 5a|x|^2 + 8a|x| - 4a, & 1 \leq |x| < 2 \\ r(x) &= 0, & \text{otherwise} \end{aligned}$$

with 'a' set to -1.0.

A neighborhood extending one sample to the left of and above the central sample, and two samples to the right of and below the central sample is required to perform bicubic interpolation.

This implementation creates an InterpolationTable whose integer coefficients have eight bits of precision to the right of the binary point.

The diagrams below illustrate the pixels involved in one-dimensional interpolation.

The diagram below illustrates the pixels involved in two-dimensional interpolation.

The class is marked 'final' so that it may be more easily inlined.

## javax.media.jai Class InterpolationBilinear

```
java.lang.Object
|
+-- javax.media.jai.Interpolation
|   |
+-- javax.media.jai.InterpolationBilinear
```

---

public final class **InterpolationBilinear**  
extends `Interpolation`

A class representing bilinear interpolation. The class is marked 'final' so it may be either automatically or manually inlined. Bilinear interpolation requires a neighborhood extending one pixel to the right and below the central sample. If the subsample position is given by (u, v), the resampled pixel value will be:

$$(1 - v) * [(1 - u) * p_{00} + u * p_{01}] + v * [(1 - u) * p_{10} + u * p_{11}]$$

A neighborhood extending one sample to the right of, and one sample below the central sample is required to perform bilinear interpolation. This implementation maintains equal subsampleBits in x and y.

The diagrams below illustrate the pixels involved in one-dimensional bilinear interpolation.

Horizontal	Vertical
$\begin{array}{ccc} s_0 & . & s_1 \\ & \wedge & \\ & x_{frac} & \end{array}$	$\begin{array}{ccc} s_0 \\ . < y_{frac} \\ s_1 \end{array}$

The diagram below illustrates the pixels involved in two-dimensional bilinear interpolation.

$$\begin{array}{ccccc} s_{00} & & s_{01} & & \\ & & . & < y_{frac} & \\ s_{10} & & s_{11} & & \\ & & \wedge & & \\ & & x_{frac} & & \end{array}$$

The class is marked 'final' so that it may be more easily inlined.

## DEFAULT\_SUBSAMPLE\_BITS

static final int **DEFAULT\_SUBSAMPLE\_BITS**

### Constructor Detail

#### InterpolationBilinear

public **InterpolationBilinear**(int subsampleBits)

Constructs an InterpolationBilinear with a given subsample precision, in bits. This precision is applied to both axes.

**Parameters:**

subsampleBits - the subsample precision.

#### InterpolationBilinear

public **InterpolationBilinear**()

Constructs an InterpolationBilinear with the default subsample precision.

### Method Detail

#### interpolateH

public final int **interpolateH**(int[] samples,  
int xfrac)

Performs horizontal interpolation on a one-dimensional array of integral samples.

**Parameters:**

samples - an array of ints.

xfrac - the subsample position, multiplied by  $2^{(\text{subsampleBits})}$ .

**Returns:**

the interpolated value as an int.

**Overrides:**

interpolateH in class Interpolation

#### interpolateV

public final int **interpolateV**(int[] samples,  
int yfrac)

Performs vertical interpolation on a one-dimensional array of integral samples.

**Parameters:**

samples - an array of ints.

yfrac - the Y subsample position, multiplied by  $2^{(\text{subsampleBits})}$ .

**Returns:**

the interpolated value as an int.

**Overrides:**

interpolateV in class Interpolation

#### interpolate

public final int **interpolate**(int[][] samples,  
int xfrac,  
int yfrac)

Performs interpolation on a two-dimensional array of integral samples.

**Parameters:**

samples - a two-dimensional array of ints.

xfrac - the X subsample position, multiplied by  $2^{(\text{subsampleBits})}$ .

yfrac - the Y subsample position, multiplied by  $2^{(\text{subsampleBits})}$ .

**Returns:**

the interpolated value as an int.

**Overrides:**

interpolate in class Interpolation

## interpolateH

```
public final int interpolateH(int s0,  
                               int s1,  
                               int xfrac)
```

Performs horizontal interpolation on a pair of integral samples. This method may be used instead of the array version for speed.

**Parameters:**

s0 - the central sample.  
s1 - the sample to the right of the central sample.  
xfrac - the subsample position, multiplied by  $2^{(\text{subsampleBits})}$ .

**Returns:**

the interpolated value as an int.

**Overrides:**

interpolateH in class Interpolation

---

## interpolateV

```
public final int interpolateV(int s0,  
                               int s1,  
                               int yfrac)
```

Performs vertical interpolation on a pair of integral samples. This method may be used instead of the array version for speed.

**Parameters:**

s0 - the central sample.  
s1 - the sample below the central sample.  
yfrac - the Y subsample position, multiplied by  $2^{(\text{subsampleBits})}$ .

**Returns:**

the interpolated value as an int.

**Overrides:**

interpolateV in class Interpolation

---

## interpolateH

```
public final int interpolateH(int s_  
                               int s0,  
                               int s1,  
                               int s2,  
                               int xfrac)
```

Performs horizontal interpolation on a quadruple of integral samples. The outlying samples are ignored.

**Overrides:**

interpolateH in class Interpolation

---

## interpolateV

```
public final int interpolateV(int s_  
                               int s0,  
                               int s1,  
                               int s2,  
                               int yfrac)
```

Performs vertical interpolation on a quadruple of integral samples. The outlying samples are ignored.

**Overrides:**

interpolateV in class Interpolation

---

## interpolate

```
public final int interpolate(int s00,  
                              int s01,  
                              int s10,  
                              int s11,  
                              int xfrac,  
                              int yfrac)
```

Performs interpolation on a 2x2 grid of integral samples.

**Parameters:**

s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and to the right of the central sample.

xfrac - the X subsample position, multiplied by  $2^{(\text{subsampleBits})}$ .  
yfrac - the Y subsample position, multiplied by  $2^{(\text{subsampleBits})}$ .

**Returns:**  
the interpolated value as an int.

**Overrides:**  
interpolate in class Interpolation

---

## interpolate

```
public final int interpolate(int s_,
                             int s_0,
                             int s_1,
                             int s_2,
                             int s0_,
                             int s00,
                             int s01,
                             int s02,
                             int s1_,
                             int s10,
                             int s11,
                             int s12,
                             int s2_,
                             int s20,
                             int s21,
                             int s22,
                             int xfrac,
                             int yfrac)
```

Performs interpolation on a 4x4 grid of integral samples. The outlying samples are ignored.

**Overrides:**  
interpolate in class Interpolation

---

## interpolateH

```
public final float interpolateH(float[] samples,
                                 float xfrac)
```

Performs horizontal interpolation on a one-dimensional array of floating-point samples.

**Parameters:**  
samples - an array of floats.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).

**Returns:**  
the interpolated value as a float.

**Overrides:**  
interpolateH in class Interpolation

---

## interpolateV

```
public final float interpolateV(float[] samples,
                                 float yfrac)
```

Performs vertical interpolation on a one-dimensional array of floating-point samples.

**Parameters:**  
samples - an array of floats.  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**  
the interpolated value as a float.

**Overrides:**  
interpolateV in class Interpolation

---

## interpolate

```
public final float interpolate(float[][] samples,
                                float xfrac,
                                float yfrac)
```

Performs interpolation on a two-dimensional array of floating-point samples.

**Parameters:**  
samples - an array of floats.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**  
the interpolated value as a float.  
**Overrides:**  
interpolate in class Interpolation

---

## interpolateH

```
public final float interpolateH(float s0,  
                                float s1,  
                                float xfrac)
```

Performs horizontal interpolation on a horizontal pair of floating-point samples. This method may be used instead of the array version for speed.

**Parameters:**  
s0 - the central sample.  
s1 - the sample to the right of the central sample.  
xfrac - the subsample position, in the range [0.0F, 1.0F).

**Returns:**  
the interpolated value as a float.

**Overrides:**  
interpolateH in class Interpolation

---

## interpolateV

```
public final float interpolateV(float s0,  
                                float s1,  
                                float yfrac)
```

Performs vertical interpolation on a vertical pair of floating-point samples. This method may be used instead of the array version for speed.

**Parameters:**  
s0 - the central sample.  
s1 - the sample below the central sample.  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**  
the interpolated value as a float.

**Overrides:**  
interpolateV in class Interpolation

---

## interpolateH

```
public final float interpolateH(float s_  
                                float s0,  
                                float s1,  
                                float s2,  
                                float frac)
```

Performs horizontal interpolation on a horizontal quad of floating-point samples. The outlying samples are ignored.

**Overrides:**  
interpolateH in class Interpolation

---

## interpolateV

```
public final float interpolateV(float s_  
                                float s0,  
                                float s1,  
                                float s2,  
                                float frac)
```

Performs vertical interpolation on a horizontal quad of floating-point samples. The outlying samples are ignored.

**Overrides:**  
interpolateV in class Interpolation

---

## interpolate

```
public final float interpolate(float s00,  
                                float s01,  
                                float s10,  
                                float s11,  
                                float xfrac,  
                                float yfrac)
```

Performs interpolation on a 2x2 grid of floating-point samples.

**Parameters:**

s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and to the right of the central sample.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

**Overrides:**

interpolate in class Interpolation

---

## interpolate

```
public final float interpolate(float s__,
                                float s_0,
                                float s_1,
                                float s_2,
                                float s0_,
                                float s00,
                                float s01,
                                float s02,
                                float s1_,
                                float s10,
                                float s11,
                                float s12,
                                float s2_,
                                float s20,
                                float s21,
                                float s22,
                                float xfrac,
                                float yfrac)
```

Performs interpolation on a 4x4 grid. The outlying samples are ignored.

**Overrides:**

interpolate in class Interpolation

---

## interpolateH

```
public final double interpolateH(double[] samples,
                                   float xfrac)
```

Performs horizontal interpolation on a one-dimensional array of double samples.

**Parameters:**

samples - an array of doubles.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

**Overrides:**

interpolateH in class Interpolation

---

## interpolateV

```
public final double interpolateV(double[] samples,
                                   float yfrac)
```

Performs vertical interpolation on a one-dimensional array of double samples.

**Parameters:**

samples - an array of doubles.  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

**Overrides:**

interpolateV in class Interpolation

---

## interpolate

```
public final double interpolate(double[][] samples,  
                                float xfrac,  
                                float yfrac)
```

Performs interpolation on a two-dimensional array of double samples.

**Parameters:**

`samples` - an array of doubles.  
`xfrac` - the X subsample position, in the range [0.0F, 1.0F).  
`yfrac` - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

**Overrides:**

`interpolate` in class `Interpolation`

---

## interpolateH

```
public final double interpolateH(double s0,  
                                double s1,  
                                float xfrac)
```

Performs horizontal interpolation on a horizontal pair of double samples. This method may be used instead of the array version for speed.

**Parameters:**

`s0` - the central sample.  
`s1` - the sample to the right of the central sample.  
`xfrac` - the subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

**Overrides:**

`interpolateH` in class `Interpolation`

---

## interpolateV

```
public final double interpolateV(double s0,  
                                double s1,  
                                float yfrac)
```

Performs vertical interpolation on a vertical pair of double samples. This method may be used instead of the array version for speed.

**Parameters:**

`s0` - the central sample.  
`s1` - the sample below the central sample.  
`yfrac` - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

**Overrides:**

`interpolateV` in class `Interpolation`

---

## interpolateH

```
public final double interpolateH(double s_  
                                double s0,  
                                double s1,  
                                double s2,  
                                float xfrac)
```

Performs interpolation on a horizontal quad of double samples. The outlying samples are ignored.

**Overrides:**

`interpolateH` in class `Interpolation`

---

## interpolateV

```
public final double interpolateV(double s_  
                                double s0,  
                                double s1,  
                                double s2,  
                                float yfrac)
```

Performs vertical interpolation on a vertical quad of double samples. The outlying samples are ignored.

**Overrides:**

interpolateV in class Interpolation

---

## interpolate

```
public final double interpolate(double s00,  
                                double s01,  
                                double s10,  
                                double s11,  
                                float xfrac,  
                                float yfrac)
```

Performs interpolation on a 2x2 grid of double samples.

**Parameters:**

s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and to the right of the central sample.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

**Overrides:**

interpolate in class Interpolation

---

## interpolate

```
public final double interpolate(double s__,  
                                double s_0,  
                                double s_1,  
                                double s_2,  
                                double s0_,  
                                double s00,  
                                double s01,  
                                double s02,  
                                double s1_,  
                                double s10,  
                                double s11,  
                                double s12,  
                                double s2_,  
                                double s20,  
                                double s21,  
                                double s22,  
                                float xfrac,  
                                float yfrac)
```

Performs interpolation on a 4x4 grid. The outlying samples are ignored.

**Overrides:**

interpolate in class Interpolation

---

## javax.media.jai Class InterpolationNearest

```
java.lang.Object
|
+-- javax.media.jai.Interpolation
|   |
|   +-- javax.media.jai.InterpolationNearest
```

---

public final class **InterpolationNearest**  
extends Interpolation

A class representing nearest-neighbor interpolation. Since nearest-neighbor interpolation is simply pixel copying, and not really interpolation at all, most code that performs nearest-neighbor sampling will want to use special-purpose code. However, this class is provided both as a way to specify such interpolation, with the consumer making use of 'instanceof' to detect the particular class, and as a way to force general Interpolation users to use nearest-neighbor sampling.

Neighborhoods of sizes 2x1, 1x2, 2x2, 4x1, 1x4, 4x4, Nx1 and 1xN, that is, all the interpolate() methods defined in the Interpolation class, are supported in the interest of simplifying code that handles a number of types of interpolation. In each case, the central sample is returned and the rest are ignored.

The class is marked 'final' so that it may be more easily inlined.

---

### Constructor Detail

#### InterpolationNearest

```
public InterpolationNearest()
```

Constructs an InterpolationNearest. The return value of getSubsampleBitsH() and getSubsampleBitsV() will be 0.

---

### Method Detail

#### interpolateH

```
public final int interpolateH(int[] samples,  
                               int xfrac)
```

Performs horizontal interpolation on a one-dimensional array of integral samples. The central sample (samples[0]) is returned.

**Overrides:**  
interpolateH in class Interpolation

---

#### interpolateV

```
public final int interpolateV(int[] samples,  
                               int yfrac)
```

Performs vertical interpolation on a one-dimensional array of integral samples. The central sample (samples[0]) is returned.

**Overrides:**  
interpolateV in class Interpolation

---

#### interpolate

```
public final int interpolate(int[][] samples,  
                              int xfrac,  
                              int yfrac)
```

Performs interpolation on a two-dimensional array of integral samples. The central sample (samples[0][0]) is returned.

**Overrides:**  
interpolate in class Interpolation

---

## interpolateH

```
public final int interpolateH(int s0,  
                               int s1,  
                               int xfrac)
```

Performs horizontal interpolation on a pair of integral samples. The central sample (s0) is returned.

**Overrides:**

interpolateH in class Interpolation

---

## interpolateV

```
public final int interpolateV(int s0,  
                               int s1,  
                               int yfrac)
```

Performs vertical interpolation on a pair of integral samples. The central sample (s0) is returned.

**Overrides:**

interpolateV in class Interpolation

---

## interpolate

```
public int interpolate(int s00,  
                       int s01,  
                       int s10,  
                       int s11,  
                       int xfrac,  
                       int yfrac)
```

Performs interpolation on a 2x2 grid of integral samples. The central sample (s00) is returned.

**Overrides:**

interpolate in class Interpolation

---

## interpolate

```
public int interpolate(int s__,  
                       int s_0,  
                       int s_1,  
                       int s_2,  
                       int s0_,  
                       int s00,  
                       int s01,  
                       int s02,  
                       int s1_,  
                       int s10,  
                       int s11,  
                       int s12,  
                       int s2_,  
                       int s20,  
                       int s21,  
                       int s22,  
                       int xfrac,  
                       int yfrac)
```

Performs interpolation on a 4x4 grid of integral samples. The central sample (s00) is returned.

**Overrides:**

interpolate in class Interpolation

---

## interpolateH

```
public final float interpolateH(float[] samples,  
                                 float xfrac)
```

Performs horizontal interpolation on a one-dimensional array of floating-point samples. The central sample (s0) is returned.

**Overrides:**

interpolateH in class Interpolation

---

## interpolateV

```
public final float interpolateV(float[] samples,  
                                float yfrac)
```

Performs vertical interpolation on a one-dimensional array of floating-point samples. The central sample (s0) is returned.

**Overrides:**

interpolateV in class Interpolation

---

## interpolate

```
public final float interpolate(float[][] samples,  
                                float xfrac,  
                                float yfrac)
```

Performs interpolation on a two-dimensional array of floating-point samples. The central sample (samples[0][0]) is returned.

**Overrides:**

interpolate in class Interpolation

---

## interpolateH

```
public final float interpolateH(float s0,  
                                float s1,  
                                float xfrac)
```

Performs horizontal interpolation on a pair of floating-point samples. The central sample (s0) is returned.

**Overrides:**

interpolateH in class Interpolation

---

## interpolateV

```
public final float interpolateV(float s0,  
                                float s1,  
                                float yfrac)
```

Performs vertical interpolation on a pair of floating-point samples. The central sample (s0) is returned.

**Overrides:**

interpolateV in class Interpolation

---

## interpolate

```
public float interpolate(float s00,  
                        float s01,  
                        float s10,  
                        float s11,  
                        float xfrac,  
                        float yfrac)
```

Performs interpolation on a 2x2 grid of floating-point samples. The central sample (s00) is returned.

**Overrides:**

interpolate in class Interpolation

---

## interpolate

```
public float interpolate(float s__,  
                        float s_0,  
                        float s_1,  
                        float s_2,  
                        float s0_,  
                        float s00,  
                        float s01,  
                        float s02,  
                        float s1_,  
                        float s10,  
                        float s11,  
                        float s12,  
                        float s2_,  
                        float s20,  
                        float s21,  
                        float s22,  
                        float xfrac,  
                        float yfrac)
```

Performs interpolation on a 4x4 grid of floating-point samples. The central sample (s00) is returned.

**Overrides:**  
interpolate in class Interpolation

---

## interpolateH

```
public final double interpolateH(double[] samples,  
                                  float xfrac)
```

Performs horizontal interpolation on a one-dimensional array of double samples. The central sample (s0) is returned.

**Overrides:**  
interpolateH in class Interpolation

---

## interpolateV

```
public final double interpolateV(double[] samples,  
                                  float yfrac)
```

Performs vertical interpolation on a one-dimensional array of double samples. The central sample (s0) is returned.

**Overrides:**  
interpolateV in class Interpolation

---

## interpolate

```
public final double interpolate(double[][] samples,  
                                float xfrac,  
                                float yfrac)
```

Performs interpolation on a two-dimensional array of double samples. The central sample (samples[0][0]) is returned.

**Overrides:**  
interpolate in class Interpolation

---

## interpolateH

```
public final double interpolateH(double s0,  
                                  double s1,  
                                  float xfrac)
```

Performs horizontal interpolation on a pair of double samples. The central sample (s0) is returned.

**Overrides:**  
interpolateH in class Interpolation

---

## interpolateV

```
public final double interpolateV(double s0,  
                                  double s1,  
                                  float yfrac)
```

Performs vertical interpolation on a pair of double samples. The central sample (s0) is returned.

**Overrides:**  
interpolateV in class Interpolation

---

## interpolate

```
public double interpolate(double s00,  
                           double s01,  
                           double s10,  
                           double s11,  
                           float xfrac,  
                           float yfrac)
```

Performs interpolation on a 2x2 grid of double samples. The central sample (s00) is returned.

**Overrides:**  
interpolate in class Interpolation

---

## **interpolate**

```
public double interpolate(double s__,
                          double s_0,
                          double s_1,
                          double s_2,
                          double s0_,
                          double s00,
                          double s01,
                          double s02,
                          double s1_,
                          double s10,
                          double s11,
                          double s12,
                          double s2_,
                          double s20,
                          double s21,
                          double s22,
                          float xfrac,
                          float yfrac)
```

Performs interpolation on a 4x4 grid of double samples. The central sample (s00) is returned.

### **Overrides:**

interpolate in class Interpolation

---

## javax.media.jai Class InterpolationTable

```
java.lang.Object
|
+-- javax.media.jai.Interpolation
|
+-- javax.media.jai.InterpolationTable
```

### Direct Known Subclasses:

InterpolationBicubic, InterpolationBicubic2

---

public class **InterpolationTable**  
extends **Interpolation**

A subclass of **Interpolation** that uses tables to store the interpolation kernels. The set of subpixel positions is broken up into a fixed number of "bins" and a distinct kernel is used for each bin. The number of bins must be a power of two.

An **InterpolationTable** defines a separable interpolation, with a set of kernels for each dimension. The number of bins may vary between the two dimensions. The kernels are stored in double precision, floating- and fixed-point form. The fixed point representation has a user-specified fractional precision. It is the user's responsibility to specify an appropriate level of precision that will not cause overflow when accumulating the results of a convolution against a set of source pixels, using 32-bit integer arithmetic.

---

### Field Detail

#### precisionBits

protected int **precisionBits**

The number of fractional bits used to describe filter coefficients.

---

#### round

private int **round**

The number 1/2 with precisionBits of fractional precision.

---

#### numSubsamplesH

private int **numSubsamplesH**

The number of horizontal subpixel positions within a pixel.

---

#### numSubsamplesV

private int **numSubsamplesV**

The number of vertical subpixel positions within a pixel.

---

#### dataHd

protected double[] **dataHd**

The horizontal coefficient data in double format.

---

#### dataVd

protected double[] **dataVd**

The vertical coefficient data in double format.

---

## dataHf

protected float[] **dataHf**

The horizontal coefficient data in floating-point format.

---

## dataVf

protected float[] **dataVf**

The vertical coefficient data in floating-point format.

---

## dataHi

protected int[] **dataHi**

The horizontal coefficient data in fixed-point format.

---

## dataVi

protected int[] **dataVi**

The vertical coefficient data in fixed-point format.

## Constructor Detail

### InterpolationTable

```
public InterpolationTable(int leftPadding,
                          int topPadding,
                          int width,
                          int height,
                          int subsampleBitsH,
                          int subsampleBitsV,
                          int precisionBits,
                          int[] dataH,
                          int[] dataV)
```

Constructs an InterpolationTable with specified horizontal and vertical extents (support), number of horizontal and vertical bins, fixed-point fractional precision, and int kernel entries. The kernel data values are organized as 2 `subsampleBits` entries each containing width ints.

dataH and dataV are required to contain width \* 2 `subsampleBitsH` and height \* 2 `subsampleBitsV` entries respectively, otherwise an IllegalArgumentException will be thrown.

If dataV is null, it is assumed to be a copy of dataH and the topPadding, height, and subsampleBitsV parameters are ignored.

#### Parameters:

leftPadding - The number of samples to the left of the central sample to be used during horizontal resampling.

topPadding - The number of samples above the central sample to be used during vertical resampling.

width - the width of a horizontal resampling kernel.

height - the height of a vertical resampling kernel. Ignored if dataV is null.

subsampleBitsH - the log (base 2) of the number of horizontal subsample positions.

subsampleBitsV - the log (base 2) of the number of vertical subsample positions. Ignored if dataV is null.

precisionBits - the number of bits of fractional precision to be used when resampling integral sample values. The same value is used for both horizontal and vertical resampling.

dataH - the horizontal table entries, as an int array of 2 `subsampleBitsH` entries each of length width.

dataV - the vertical table entries, as an int array of 2 `subsampleBitsV` entries each of length height, or null. If null, the dataH table is used for vertical interpolation as well and the topPadding, height, and subsampleBitsV parameters are ignored.

#### Throws:

java.lang.IllegalArgumentException - if the size of the data arrays are incorrect.

---

### InterpolationTable

```
public InterpolationTable(int padding,
                          int width,
                          int subsampleBits,
                          int precisionBits,
                          int[] data)
```

Constructs an InterpolationTable with identical horizontal and vertical resampling kernels.

**Parameters:**

padding - The number of samples to the left or above the central sample to be used during resampling.  
width - the width or height of a resampling kernel.  
subsampleBits - the log (base 2) of the number of subsample positions.  
precisionBits - the number of bits of fractional precision to be used when resampling integral sample values.  
data - the kernel entries, as an int array of width\*2<sup>subsampleBits</sup> entries

---

## InterpolationTable

```
public InterpolationTable(int leftPadding,
                          int topPadding,
                          int width,
                          int height,
                          int subsampleBitsH,
                          int subsampleBitsV,
                          int precisionBits,
                          float[] dataH,
                          float[] dataV)
```

Constructs an InterpolationTable with specified horizontal and vertical extents (support), number of horizontal and vertical bins, fixed-point fractional precision, and float kernel entries. The kernel data values are organized as 2<sup>subsampleBits</sup> entries each containing width floats.

dataH and dataV are required to contain width \* 2<sup>subsampleBitsH</sup> and height \* 2<sup>subsampleBitsV</sup> entries respectively, otherwise an IllegalArgumentException will be thrown.

If dataV is null, it is assumed to be a copy of dataH and the topPadding, height, and subsampleBitsV parameters are ignored.

**Parameters:**

leftPadding - The number of samples to the left of the central sample to be used during horizontal resampling.  
topPadding - The number of samples above the central sample to be used during vertical resampling.  
width - the width of a horizontal resampling kernel.  
height - the height of a vertical resampling kernel. Ignored if dataV is null.  
subsampleBitsH - the log (base 2) of the number of horizontal subsample positions.  
subsampleBitsV - the log (base 2) of the number of vertical subsample positions. Ignored if dataV is null.  
precisionBits - the number of bits of fractional precision to be used when resampling integral sample values. The same value is used for both horizontal and vertical resampling.  
dataH - the horizontal table entries, as a float array of 2<sup>subsampleBitsH</sup> entries each of length width.  
dataV - the vertical table entries, as a float array of 2<sup>subsampleBitsV</sup> entries each of length height, or null. If null, the dataH table is used for vertical interpolation as well and the topPadding, height, and subsampleBitsV parameters are ignored.

**Throws:**

java.lang.IllegalArgumentException - if the size of the data arrays are incorrect.

---

## InterpolationTable

```
public InterpolationTable(int padding,
                          int width,
                          int subsampleBits,
                          int precisionBits,
                          float[] data)
```

Constructs an InterpolationTable with identical horizontal and vertical resampling kernels.

**Parameters:**

padding - The number of samples to the left or above the central sample to be used during resampling.  
width - the width or height of a resampling kernel.  
subsampleBits - the log (base 2) of the number of subsample positions.  
precisionBits - the number of bits of fractional precision to be used when resampling integral sample values.  
data - the kernel entries, as a float array of width\*2<sup>subsampleBits</sup> entries

---

## InterpolationTable

```
public InterpolationTable(int leftPadding,
                          int topPadding,
                          int width,
                          int height,
                          int subsampleBitsH,
                          int subsampleBitsV,
                          int precisionBits,
                          double[] dataH,
                          double[] dataV)
```

Constructs an InterpolationTable with specified horizontal and vertical extents (support), number of horizontal and vertical bins, fixed-point fractional precision, and double kernel entries. The kernel data values are organized as  $2^{\text{subsampleBits}}$  entries each containing width doubles.

dataH and dataV are required to contain  $\text{width} * 2^{\text{subsampleBitsH}}$  and  $\text{height} * 2^{\text{subsampleBitsV}}$  entries respectively, otherwise an IllegalArgumentException will be thrown.

If dataV is null, it is assumed to be a copy of dataH and the topPadding, height, and subsampleBitsV parameters are ignored.

**Parameters:**

leftPadding - The number of samples to the left of the central sample to be used during horizontal resampling.

topPadding - The number of samples above the central sample to be used during vertical resampling.

width - the width of a horizontal resampling kernel.

height - the height of a vertical resampling kernel. Ignored if dataV is null.

subsampleBitsH - the log (base 2) of the number of horizontal subsample positions.

subsampleBitsV - the log (base 2) of the number of vertical subsample positions. Ignored if dataV is null.

precisionBits - the number of bits of fractional precision to be used when resampling integral sample values. The same value is used for both horizontal and vertical resampling.

dataH - the horizontal table entries, as a double array of  $2^{\text{subsampleBitsH}}$  entries each of length width.

dataV - the vertical table entries, as a double array of  $2^{\text{subsampleBitsV}}$  entries each of length height, or null. If null, the dataH table is used for vertical interpolation as well and the topPadding, height, and subsampleBitsV parameters are ignored.

---

## InterpolationTable

```
public InterpolationTable(int padding,
                          int width,
                          int subsampleBits,
                          int precisionBits,
                          double[] data)
```

Constructs an InterpolationTable with identical horizontal and vertical resampling kernels.

**Parameters:**

padding - The number of samples to the left or above the central sample to be used during resampling.

width - the width or height of a resampling kernel.

subsampleBits - the log (base 2) of the number of subsample positions.

precisionBits - the number of bits of fractional precision to be used when resampling integral sample values.

data - the kernel entries, as a double array of  $\text{width} * 2^{\text{subsampleBitsH}}$  entries

## Method Detail

### getPrecisionBits

```
public int getPrecisionBits()
```

Returns the number of bits of fractional precision used to store the fixed-point table entries.

---

### getHorizontalTableData

```
public int[] getHorizontalTableData()
```

Returns the integer (fixed-point) horizontal table data. The output is an int array of length  $\text{getWidth()} * 2^{\text{getSubsampleBitsH()}}$ .

The following code, given an instance interp of class InterpolationTable, will perform interpolation of a set of  $\text{getWidth()}$  samples at a given fractional position (bin) xfrac between 0 and  $2^{\text{getSubsampleBitsH()}} - 1$ :

```
int interpolateH(InterpolationTable interp, int[] samples, int xfrac) {
    int[] dataH = interp.getHorizontalTableData();
    int precisionBits = interp.getPrecisionBits();
    int round = 1 << (precisionBits - 1);
    int width = interp.getWidth();
    int offset = width*xfrac;

    int sum = 0;
    for (int i = 0; i < width; i++) {
        sum += dataH[offset + i]*samples[i];
    }
    return (sum + round) >> precisionBits;
}
```

In practice, the values dataH, precisionBits, etc., may be extracted once and reused to interpolate multiple output pixels.

**Returns:**

An array of ints.

---

**getVerticalTableData**

```
public int[] getVerticalTableData()
```

Returns the integer (fixed-point) vertical table data. The output is an int array of length `getHeight() * 2getSubsampleBitsV()`.

The following code, given an instance `interp` of class `InterpolationTable`, will perform interpolation of a set of `getHeight()` samples at a given fractional position (bin) `yfrac` between 0 and `2getSubsampleBitsV() - 1`:

```
int interpolateV(InterpolationTable interp, int[] samples, int yfrac) {
    int[] dataV = interp.getVerticalTableData();
    int precisionBits = interp.getPrecisionBits();
    int round = 1 << (precisionBits - 1);
    int height = interp.getHeight();
    int offset = height*yfrac;

    int sum = 0;
    for (int i = 0; i < height; i++) {
        sum += dataV[offset + i]*samples[i];
    }
    return (sum + round) >> precisionBits;
}
```

In practice, the values `dataV`, `precisionBits`, etc., may be extracted once and reused to interpolate multiple output pixels.

**Returns:**

An array of ints.

---

**getHorizontalTableDataFloat**

```
public float[] getHorizontalTableDataFloat()
```

Returns the floating-point horizontal table data. The output is a float array of length `getWidth() * 2getSubsampleBitsH()`.

The following code, given an instance `interp` of class `InterpolationTable`, will perform interpolation of a set of `getWidth()` floating-point samples at a given fractional position `xfrac` between 0.0F and 1.0F:

```
float interpolateH(InterpolationTable interp,
                  float[] samples, float xfrac) {
    float[] dataH = interp.getHorizontalTableDataFloat();
    int width = interp.getWidth();
    int numSubsamplesH = 1 << getSubsampleBitsH();
    int ifrac = (int)(xfrac*numSubsamplesH);
    int offset = width*ifrac;

    float sum = 0.0F;
    for (int i = 0; i < width; i++) {
        sum += dataH[offset + i]*samples[i];
    }
    return sum;
}
```

In practice, the values `dataH`, `numSubsamplesH`, etc., may be extracted once and reused to interpolate multiple output pixels.

**Returns:**

An array of floats.

---

**getVerticalTableDataFloat**

```
public float[] getVerticalTableDataFloat()
```

Returns the floating-point vertical table data. The output is a float array of length `getWidth() * 2getSubsampleBitsV()`.

The following code, given an instance `interp` of class `InterpolationTable`, will perform interpolation of a set of `getHeight()` floating-point samples at a given fractional position `yfrac` between 0.0F and 1.0F:

```

float interpolateV(InterpolationTable interp,
                  float[] samples, float yfrac) {
    float[] dataV = interp.getVerticalTableDataFloat();
    int height = interp.getHeight();
    int numSubsamplesV = 1 << getSubsampleBitsV();
    int ifrac = (int)(yfrac*numSubsamplesV);
    int offset = height*ifrac;

    float sum = 0.0F;
    for (int i = 0; i < height; i++) {
        sum += dataV[offset + i]*samples[i];
    }
    return sum;
}

```

In practice, the values dataV, numSubsamplesV, etc., may be extracted once and reused to interpolate multiple output pixels.

**Returns:**

An array of floats.

---

## getHorizontalTableDataDouble

```
public double[] getHorizontalTableDataDouble()
```

Returns the double horizontal table data. The output is a double array of length getWidth() \* 2 getSubsampleBitsH() .

The following code, given an instance interp of class InterpolationTable, will perform interpolation of a set of getWidth() double samples at a given fractional position xfrac between 0.0F and 1.0F:

```

double interpolateH(InterpolationTable interp,
                   double[] samples, float xfrac) {
    double[] dataH = interp.getHorizontalTableDataDouble();
    int width = interp.getWidth();
    int numSubsamplesH = 1 << getSubsampleBitsH();
    int ifrac = (int)(xfrac*numSubsamplesH);
    int offset = width*ifrac;

    double sum = 0.0;
    for (int i = 0; i < width; i++) {
        sum += dataH[offset + i]*samples[i];
    }
    return sum;
}

```

In practice, the values dataH, numSubsamplesH, etc., may be extracted once and reused to interpolate multiple output pixels.

**Returns:**

An array of doubles.

---

## getVerticalTableDataDouble

```
public double[] getVerticalTableDataDouble()
```

Returns the double vertical table data. The output is a double array of length getHeight() \* 2 getSubsampleBitsV() ).

The following code, given an instance interp of class InterpolationTable, will perform interpolation of a set of getHeight() double samples at a given fractional position yfrac between 0.0F and 1.0F:

```

double interpolateV(InterpolationTable interp,
                   double[] samples, float yfrac) {
    double[] dataV = interp.getVerticalTableDataDouble();
    int height = interp.getHeight();
    int numSubsamplesV = 1 << getSubsampleBitsV();
    int ifrac = (int)(yfrac*numSubsamplesV);
    int offset = height*ifrac;

    double sum = 0.0;
    for (int i = 0; i < height; i++) {
        sum += dataV[offset + i]*samples[i];
    }
    return sum;
}

```

In practice, the values `dataV`, `numSubsamplesV`, etc., may be extracted once and reused to interpolate multiple output pixels.

**Returns:**

An array of doubles.

---

## interpolateH

```
public int interpolateH(int[] samples,  
                        int xfrac)
```

Performs horizontal interpolation on a one-dimensional array of integral samples. If `xfrac` does not lie between 0 and  $2^{\text{subsampleBitsH}-1}$ , an `ArrayIndexOutOfBoundsException` may occur, where width is the width of the horizontal resampling kernel.

**Parameters:**

`samples` - an array of ints.

`xfrac` - the subsample position, multiplied by  $2^{\text{subsampleBitsH}}$ .

**Returns:**

the interpolated value as an int.

**Throws:**

`ArrayIndexOutOfBoundsException` - if `xfrac` is out of bounds.

**Overrides:**

`interpolateH` in class `Interpolation`

---

## interpolateV

```
public int interpolateV(int[] samples,  
                        int yfrac)
```

Performs vertical interpolation on a one-dimensional array of integral samples. If `yfrac` does not lie between 0 and  $2^{\text{subsampleBitsV}-1}$ , an `ArrayIndexOutOfBoundsException` may occur, where height is the height of the vertical resampling kernel.

**Parameters:**

`samples` - an array of ints.

`yfrac` - the Y subsample position, multiplied by  $2^{\text{subsampleBitsV}}$ .

**Returns:**

the interpolated value as an int.

**Throws:**

`ArrayIndexOutOfBoundsException` - if `yfrac` is out of bounds.

**Overrides:**

`interpolateV` in class `Interpolation`

---

## interpolateH

```
public int interpolateH(int s0,  
                        int s1,  
                        int xfrac)
```

Performs horizontal interpolation on a pair of integral samples. This method may be used instead of the array version for speed. It should only be called if `width == 2`. If `xfrac` does not lie between 0 and  $2^{\text{subsampleBitsH}-1}$ , an `ArrayIndexOutOfBoundsException` may occur, where width is the width of the horizontal resampling kernel.

**Parameters:**

`s0` - the central sample.

`s1` - the sample to the right of the central sample.

`xfrac` - the subsample position, multiplied by  $2^{\text{subsampleBitsH}}$ .

**Returns:**

the interpolated value as an int.

**Throws:**

`ArrayIndexOutOfBoundsException` - if `xfrac` is out of bounds.

**Overrides:**

`interpolateH` in class `Interpolation`

---

## interpolateH

```
public int interpolateH(int s_  
                        int s0,  
                        int s1,  
                        int s2,  
                        int xfrac)
```

Performs horizontal interpolation on a quadruple of integral samples. This method may be used instead of the array version for speed. It should only be called if width == 4 and leftPadding == 1. If xfrac does not lie between 0 and  $2^{\text{subsampleBitsH}-1}$ , an `ArrayIndexOutOfBoundsException` may occur, where width is the width of the horizontal resampling kernel.

**Parameters:**

s\_ - the sample to the left of the central sample.  
s0 - the central sample.  
s1 - the sample to the right of the central sample.  
s2 - the sample to the right of s1.  
xfrac - the subsample position, multiplied by  $2^{\text{subsampleBitsH}}$ .

**Returns:**

the interpolated value as an int.

**Throws:**

`ArrayIndexOutOfBoundsException` - if xfrac is out of bounds.

**Overrides:**

`interpolateH` in class `Interpolation`

---

## interpolateV

```
public int interpolateV(int s0,  
                      int s1,  
                      int yfrac)
```

Performs vertical interpolation on a pair of integral samples. This method may be used instead of the array version for speed. It should only be called if height == 2 and topPadding == 0. If yfrac does not lie between 0 and  $2^{\text{subsampleBitsV}-1}$ , an `ArrayIndexOutOfBoundsException` may occur, where height is the height of the vertical resampling kernel.

**Parameters:**

s0 - the central sample.  
s1 - the sample below the central sample.  
yfrac - the Y subsample position, multiplied by  $2^{\text{subsampleBitsV}}$ .

**Returns:**

the interpolated value as an int.

**Throws:**

`ArrayIndexOutOfBoundsException` - if yfrac is out of bounds.

**Overrides:**

`interpolateV` in class `Interpolation`

---

## interpolateV

```
public int interpolateV(int s_  
                      int s0,  
                      int s1,  
                      int s2,  
                      int yfrac)
```

Performs vertical interpolation on a quadruple of integral samples. This method may be used instead of the array version for speed. It should only be called if height == 4 and topPadding == 1. If yfrac does not lie between 0 and  $2^{\text{subsampleBitsV}-1}$ , an `ArrayIndexOutOfBoundsException` may occur, where height is the height of the vertical resampling kernel.

**Parameters:**

s\_ - the sample above the central sample.  
s0 - the central sample.  
s1 - the sample below the central sample.  
s2 - the sample below s1.  
yfrac - the Y subsample position, multiplied by  $2^{\text{subsampleBitsV}}$ .

**Returns:**

the interpolated value as an int.

**Throws:**

`ArrayIndexOutOfBoundsException` - if yfrac is out of bounds.

**Overrides:**

`interpolateV` in class `Interpolation`

---

## interpolate

```
public int interpolate(int s00,  
                     int s01,  
                     int s10,  
                     int s11,  
                     int xfrac,  
                     int yfrac)
```

Performs interpolation on a 2x2 grid of integral samples. It should only be called if width == height == 2 and leftPadding == topPadding == 0. If xfrac does not lie between 0 and  $2^{\text{subsampleBitsH}-1}$ , or yfrac does not lie between 0 and  $2^{\text{subsampleBitsV}-1}$ , an `ArrayIndexOutOfBoundsException` may occur, where width and height are the width and height of the horizontal and vertical resampling kernels respectively.

**Parameters:**

s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and to the right of the central sample.  
xfrac - the X subsample position, multiplied by  $2^{\text{subsampleBitsH}}$ .  
yfrac - the Y subsample position, multiplied by  $2^{\text{subsampleBitsV}}$ .

**Returns:**

the interpolated value as an int.

**Throws:**

`ArrayIndexOutOfBoundsException` - if xfrac or yfrac are out of bounds.

**Overrides:**

interpolate in class `Interpolation`

## interpolate

```
public int interpolate(int s__,
                     int s_0,
                     int s_1,
                     int s_2,
                     int s0_,
                     int s00,
                     int s01,
                     int s02,
                     int s1_,
                     int s10,
                     int s11,
                     int s12,
                     int s2_,
                     int s20,
                     int s21,
                     int s22,
                     int xfrac,
                     int yfrac)
```

Performs interpolation on a 4x4 grid of integral samples. It should only be called if width == height == 4 and leftPadding == topPadding == 1. If xfrac does not lie between 0 and  $2^{\text{subsampleBitsH}-1}$ , or yfrac does not lie between 0 and  $2^{\text{subsampleBitsV}-1}$ , an `ArrayIndexOutOfBoundsException` may occur, where width and height are the the width and height of the horizontal and vertical resampling kernels respectively.

**Parameters:**

s\_\_ - the sample above and to the left of the central sample.  
s\_0 - the sample above the central sample.  
s\_1 - the sample above and one to the right of the central sample.  
s\_2 - the sample above and two to the right of the central sample.  
s0\_ - the sample to the left of the central sample.  
s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s02 - the sample two to the right of the central sample.  
s1\_ - the sample below and one to the left of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and one to the right of the central sample.  
s12 - the sample below and two to the right of the central sample.  
s2\_ - the sample two below and one to the left of the central sample.  
s20 - the sample two below the central sample.  
s21 - the sample two below and one to the right of the central sample.  
s22 - the sample two below and two to the right of the central sample.  
xfrac - the X subsample position, multiplied by  $2^{\text{subsampleBitsH}}$ .  
yfrac - the Y subsample position, multiplied by  $2^{\text{subsampleBitsV}}$ .

**Returns:**

the interpolated value as an int.

**Throws:**

`ArrayIndexOutOfBoundsException` - if xfrac or yfrac are out of bounds.

**Overrides:**

interpolate in class `Interpolation`

---

## interpolateF

```
public int interpolateF(int s__,
                      int s_0,
                      int s_1,
                      int s_2,
                      int s0_,
                      int s00,
                      int s01,
                      int s02,
                      int s1_,
                      int s10,
                      int s11,
                      int s12,
                      int s2_,
                      int s20,
                      int s21,
                      int s22,
                      int xfrac,
                      int yfrac)
```

Performs interpolation on a 4x4 grid of integral samples. All internal calculations are performed in floating-point. It should only be called if width == height == 4 and leftPadding == topPadding == 1. If xfrac does not lie between 0 and  $2^{\text{subsampleBitsH}-1}$ , or yfrac does not lie between 0 and  $2^{\text{subsampleBitsV}-1}$ , an `ArrayIndexOutOfBoundsException` may occur, where width and height are the width and height of horizontal and vertical resampling kernels respectively.

### Parameters:

s\_\_ - the sample above and to the left of the central sample.  
s\_0 - the sample above the central sample.  
s\_1 - the sample above and one to the right of the central sample.  
s\_2 - the sample above and two to the right of the central sample.  
s0\_ - the sample to the left of the central sample.  
s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s02 - the sample two to the right of the central sample.  
s1\_ - the sample below and one to the left of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and one to the right of the central sample.  
s12 - the sample below and two to the right of the central sample.  
s2\_ - the sample two below and one to the left of the central sample.  
s20 - the sample two below the central sample.  
s21 - the sample two below and one to the right of the central sample.  
s22 - the sample two below and two to the right of the central sample.  
xfrac - the X subsample position, multiplied by  $2^{\text{subsampleBitsH}}$ .  
yfrac - the Y subsample position, multiplied by  $2^{\text{subsampleBitsV}}$ .

### Returns:

the interpolated value as an int.

### Throws:

`ArrayIndexOutOfBoundsException` - if xfrac or yfrac are out of bounds.

---

## interpolateH

```
public float interpolateH(float[] samples,
                        float xfrac)
```

Performs horizontal interpolation on a one-dimensional array of floating-point samples representing a row of samples. If xfrac does not lie between the range [0.0, 1.0F), an `ArrayIndexOutOfBoundsException` may occur.

### Parameters:

samples - an array of floats.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).

### Returns:

the interpolated value as a float.

### Throws:

`ArrayIndexOutOfBoundsException` - if xfrac is out of bounds.

### Overrides:

interpolateH in class `Interpolation`

---

## interpolateV

```
public float interpolateV(float[] samples,  
                           float yfrac)
```

Performs vertical interpolation on a one-dimensional array of floating-point samples representing a column of samples. If yfrac does not lie between the range [0.0, 1.0F), an `ArrayIndexOutOfBoundsException` may occur.

**Parameters:**

`samples` - an array of floats.  
`yfrac` - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

**Throws:**

`ArrayIndexOutOfBoundsException` - if yfrac is out of bounds.

**Overrides:**

`interpolateV` in class `Interpolation`

---

## interpolateH

```
public float interpolateH(float s0,  
                           float s1,  
                           float xfrac)
```

Performs horizontal interpolation on a pair of floating-point samples. This method may be used instead of the array version for speed. It should only be called if width == 2. If xfrac does not lie between the range [0.0, 1.0F), an `ArrayIndexOutOfBoundsException` may occur.

**Parameters:**

`s0` - the central sample.  
`s1` - the sample to the right of the central sample.  
`xfrac` - the X subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

**Throws:**

`ArrayIndexOutOfBoundsException` - if xfrac is out of bounds.

**Overrides:**

`interpolateH` in class `Interpolation`

---

## interpolateH

```
public float interpolateH(float s_  
                           float s0,  
                           float s1,  
                           float s2,  
                           float xfrac)
```

Performs horizontal interpolation on a quadruple of floating-point samples. This method may be used instead of the array version for speed. It should only be called if width == 4 and leftPadding == 1. If xfrac does not lie between the range [0.0, 1.0F), an `ArrayIndexOutOfBoundsException` may occur.

**Parameters:**

`s_` - the sample to the left of the central sample.  
`s0` - the central sample.  
`s1` - the sample to the right of the central sample.  
`s2` - the sample to the right of s1.  
`xfrac` - the X subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

**Throws:**

`ArrayIndexOutOfBoundsException` - if xfrac is out of bounds.

**Overrides:**

`interpolateH` in class `Interpolation`

---

## interpolateV

```
public float interpolateV(float s0,  
                           float s1,  
                           float yfrac)
```

Performs vertical interpolation on a pair of floating-point samples. This method may be used instead of the array version for speed. It should only be called if height == 2 and topPadding == 0. If yfrac does not lie between the range [0.0, 1.0F), an `ArrayIndexOutOfBoundsException` may occur.

**Parameters:**

s0 - the central sample.  
s1 - the sample below the central sample.  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

**Throws:**

ArrayIndexOutOfBoundsException - if yfrac is out of bounds.

**Overrides:**

interpolateV in class Interpolation

**interpolateV**

```
public float interpolateV(float s_,
                          float s0,
                          float s1,
                          float s2,
                          float yfrac)
```

Performs vertical interpolation on a quadruple of floating-point samples. This method may be used instead of the array version for speed. It should only be called if height == 4 and topPadding == 1. If yfrac does not lie between the range [0.0, 1.0F), an ArrayIndexOutOfBoundsException may occur.

**Parameters:**

s\_ - the sample above the central sample.  
s0 - the central sample.  
s1 - the sample below the central sample.  
s2 - the sample below s1.  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

**Throws:**

ArrayIndexOutOfBoundsException - if yfrac is out of bounds.

**Overrides:**

interpolateV in class Interpolation

**interpolate**

```
public float interpolate(float s00,
                          float s01,
                          float s10,
                          float s11,
                          float xfrac,
                          float yfrac)
```

Performs interpolation on a 2x2 grid of floating-point samples. It should only be called if width == height == 2 and leftPadding == topPadding == 0. If either xfrac or yfrac does not lie between the range [0.0, 1.0F), an ArrayIndexOutOfBoundsException may occur.

**Parameters:**

s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and to the right of the central sample.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

**Throws:**

ArrayIndexOutOfBoundsException - if xfrac or yfrac are out of bounds.

**Overrides:**

interpolate in class Interpolation

**interpolate**

```
public float interpolate(float s__,
                          float s_0,
                          float s_1,
                          float s_2,
                          float s0_,
                          float s00,
                          float s01,
```

```

        float s02,
        float s1_,
        float s10,
        float s11,
        float s12,
        float s2_,
        float s20,
        float s21,
        float s22,
        float xfrac,
        float yfrac)

```

Performs interpolation on a 4x4 grid of floating-point samples. It should only be called if width == height == 4 and leftPadding == topPadding == 1. If either xfrac or yfrac does not lie between the range [0.0, 1.0F), an `ArrayIndexOutOfBoundsException` may occur.

**Parameters:**

s\_\_ - the sample above and to the left of the central sample.  
s\_0 - the sample above the central sample.  
s\_1 - the sample above and one to the right of the central sample.  
s\_2 - the sample above and two to the right of the central sample.  
s0\_ - the sample to the left of the central sample.  
s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s02 - the sample two to the right of the central sample.  
s1\_ - the sample below and one to the left of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and one to the right of the central sample.  
s12 - the sample below and two to the right of the central sample.  
s2\_ - the sample two below and one to the left of the central sample.  
s20 - the sample two below the central sample.  
s21 - the sample two below and one to the right of the central sample.  
s22 - the sample two below and two to the right of the central sample.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a float.

**Throws:**

`ArrayIndexOutOfBoundsException` - if xfrac or yfrac are out of bounds.

**Overrides:**

interpolate in class `Interpolation`

## interpolateH

```

public double interpolateH(double[] samples,
                           float xfrac)

```

Performs horizontal interpolation on a one-dimensional array of double samples representing a row of samples. If xfrac does not lie between the range [0.0, 1.0F), an `ArrayIndexOutOfBoundsException` may occur.

**Parameters:**

samples - an array of doubles.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

**Throws:**

`ArrayIndexOutOfBoundsException` - if xfrac is out of bounds.

**Overrides:**

interpolateH in class `Interpolation`

## interpolateV

```

public double interpolateV(double[] samples,
                           float yfrac)

```

Performs vertical interpolation on a one-dimensional array of double samples representing a column of samples. If yfrac does not lie between the range [0.0, 1.0F), an `ArrayIndexOutOfBoundsException` may occur.

**Parameters:**

samples - an array of doubles.  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**  
the interpolated value as a double.

**Throws:**  
ArrayIndexOutOfBoundsException - if yfrac is out of bounds.

**Overrides:**  
interpolateV in class Interpolation

---

## interpolateH

```
public double interpolateH(double s0,  
                           double s1,  
                           float xfrac)
```

Performs horizontal interpolation on a pair of double samples. This method may be used instead of the array version for speed. It should only be called if width == 2. If xfrac does not lie between the range [0.0, 1.0F), an ArrayIndexOutOfBoundsException may occur.

**Parameters:**  
s0 - the central sample.  
s1 - the sample to the right of the central sample.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).

**Returns:**  
the interpolated value as a double.

**Throws:**  
ArrayIndexOutOfBoundsException - if xfrac is out of bounds.

**Overrides:**  
interpolateH in class Interpolation

---

## interpolateH

```
public double interpolateH(double s_  
                           double s0,  
                           double s1,  
                           double s2,  
                           float xfrac)
```

Performs horizontal interpolation on a quadruple of double samples. This method may be used instead of the array version for speed. It should only be called if width == 4 and leftPadding == 1. If xfrac does not lie between the range [0.0, 1.0F), an ArrayIndexOutOfBoundsException may occur.

**Parameters:**  
s\_ - the sample to the left of the central sample.  
s0 - the central sample.  
s1 - the sample to the right of the central sample.  
s2 - the sample to the right of s1.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).

**Returns:**  
the interpolated value as a double.

**Throws:**  
ArrayIndexOutOfBoundsException - if xfrac is out of bounds.

**Overrides:**  
interpolateH in class Interpolation

---

## interpolateV

```
public double interpolateV(double s0,  
                           double s1,  
                           float yfrac)
```

Performs vertical interpolation on a pair of double samples. This method may be used instead of the array version for speed. It should only be called if height == 2 and topPadding == 0. If yfrac does not lie between the range [0.0, 1.0F), an ArrayIndexOutOfBoundsException may occur.

**Parameters:**  
s0 - the central sample.  
s1 - the sample below the central sample.  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**  
the interpolated value as a double.

**Throws:**  
ArrayIndexOutOfBoundsException - if yfrac is out of bounds.

**Overrides:**  
interpolateV in class Interpolation

---

## interpolateV

```
public double interpolateV(double s_,  
                           double s0,  
                           double s1,  
                           double s2,  
                           float yfrac)
```

Performs vertical interpolation on a quadruple of double samples. This method may be used instead of the array version for speed. It should only be called if height == 4 and topPadding == 1. If yfrac does not lie between the range [0.0, 1.0F), an `ArrayIndexOutOfBoundsException` may occur.

**Parameters:**

s\_ - the sample above the central sample.  
s0 - the central sample.  
s1 - the sample below the central sample.  
s2 - the sample below s1.  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

**Throws:**

`ArrayIndexOutOfBoundsException` - if yfrac is out of bounds.

**Overrides:**

interpolateV in class Interpolation

---

## interpolate

```
public double interpolate(double s00,  
                          double s01,  
                          double s10,  
                          double s11,  
                          float xfrac,  
                          float yfrac)
```

Performs interpolation on a 2x2 grid of double samples. It should only be called if width == height == 2 and leftPadding == topPadding == 0. If either xfrac or yfrac does not lie between the range [0.0, 1.0F), an `ArrayIndexOutOfBoundsException` may occur.

**Parameters:**

s00 - the central sample.  
s01 - the sample to the right of the central sample.  
s10 - the sample below the central sample.  
s11 - the sample below and to the right of the central sample.  
xfrac - the X subsample position, in the range [0.0F, 1.0F).  
yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

**Throws:**

`ArrayIndexOutOfBoundsException` - if xfrac or yfrac are out of bounds.

**Overrides:**

interpolate in class Interpolation

---

## interpolate

```
public double interpolate(double s__,  
                          double s_0,  
                          double s_1,  
                          double s_2,  
                          double s0_,  
                          double s00,  
                          double s01,  
                          double s02,  
                          double s1_,  
                          double s10,  
                          double s11,  
                          double s12,  
                          double s2_,  
                          double s20,
```

```

double s21,
double s22,
float xfrac,
float yfrac)

```

Performs interpolation on a 4x4 grid of double samples. It should only be called if width == height == 4 and leftPadding == topPadding == 1. If either xfrac or yfrac does not lie between the range [0.0, 1.0F), an `ArrayIndexOutOfBoundsException` may occur.

**Parameters:**

s\_\_ - the sample above and to the left of the central sample.  
 s\_0 - the sample above the central sample.  
 s\_1 - the sample above and one to the right of the central sample.  
 s\_2 - the sample above and two to the right of the central sample.  
 s0\_ - the sample to the left of the central sample.  
 s00 - the central sample.  
 s01 - the sample to the right of the central sample.  
 s02 - the sample two to the right of the central sample.  
 s1\_ - the sample below and one to the left of the central sample.  
 s10 - the sample below the central sample.  
 s11 - the sample below and one to the right of the central sample.  
 s12 - the sample below and two to the right of the central sample.  
 s2\_ - the sample two below and one to the left of the central sample.  
 s20 - the sample two below the central sample.  
 s21 - the sample two below and one to the right of the central sample.  
 s22 - the sample two below and two to the right of the central sample.  
 xfrac - the X subsample position, in the range [0.0F, 1.0F).  
 yfrac - the Y subsample position, in the range [0.0F, 1.0F).

**Returns:**

the interpolated value as a double.

**Throws:**

`ArrayIndexOutOfBoundsException` - if xfrac or yfrac are out of bounds.

**Overrides:**

interpolate in class `Interpolation`

---

## javax.media.jai Class JAI.RenderingKey

```
java.lang.Object
|
+-- java.awt.RenderingHints.Key
|
+-- javax.media.jai.JAI.RenderingKey
```

---

static class **JAI.RenderingKey**  
extends java.awt.RenderingHints.Key  
Rendering hints.

---

### Field Detail

#### objectClass

private java.lang.Class **objectClass**

### Constructor Detail

#### JAI.RenderingKey

```
JAI.RenderingKey(int privateKey,  
                  java.lang.Class objectClass)
```

### Method Detail

#### isCompatibleValue

```
public boolean isCompatibleValue(java.lang.Object val)
```

##### Overrides:

isCompatibleValue in class java.awt.RenderingHints.Key

---

## javax.media.jai

### Class JAI

```
java.lang.Object
|
+-- javax.media.jai.JAI
```

---

```
public final class JAI
    extends java.lang.Object
```

A convenience class for instantiating operations.

This class allows programmers to use the syntax:

```
import javax.media.jai.JAI;
RenderedOp im = JAI.create("convolve", paramBlock, renderHints);
```

to create new images or collections by applying operators. The `create()` method returns a `RenderedOp` encapsulating the operation name, parameter block, and rendering hints. Additionally, it performs validity checking on the operation parameters.

If the `OperationDescriptor` associated with the named operation returns `true` from its `isImmediate()` method, the `JAI.createNS()` method will ask the `RenderedOp` it constructs to render itself immediately. If this rendering is `null`, `createNS()` will itself return `null` rather than returning an instance of `RenderedOp` as it normally does.

It is possible to create new instances of the `JAI` class in order to control each instance's registry and tile scheduler individually. Most users will want to use only the static methods of this class, which perform all operations on a default instance, which in turn makes use of a default registry. To create a new image or collection on a non-default `JAI` instance, the `createNS()` and `createCollectionNS` (NS being short for "non-static") methods are used.

The `JAI` class contains convenience methods for a number of common argument list formats. These methods perform the work of constructing a `ParameterBlock` automatically. The convenience methods are available only in static form and make use of the default instance. When operating with a specific instance, the general, non-static functions `createNS()` and `createCollectionNS()` should be used. All of the convenience methods operate by calling `createNS()` on the default `JAI` instance, and thus inherit the semantics of that method with regard to immediate rendering.

The registry being used by a particular instance may be inspected or set using the `getOperationRegistry()` and `setOperationRegistry()` methods. Only experienced users should attempt to set the registry.

The `TileCache` and `TileScheduler` associated with an instance may be similarly accessed.

Each instance of `JAI` contains a set of rendering hints which will be used for all image or collection creations. These hints are merged with any hints supplied to the `create` method; directly supplied hints take precedence over the common hints. When a new `JAI` instance is constructed, its hints are initialized to a copy of the hints associated with the default instance. The hints associated with any instance, including the default instance, may be manipulated using the `getRenderingHints()`, `setRenderingHints()`,

<b>Field Detail</b>
---------------------

#### **HINT\_IMAGE\_LAYOUT**

```
private static final int HINT_IMAGE_LAYOUT
```

---

#### **HINT\_INTERPOLATION**

```
private static final int HINT_INTERPOLATION
```

---

#### **HINT\_OPERATION\_REGISTRY**

```
private static final int HINT_OPERATION_REGISTRY
```

---

#### **HINT\_OPERATION\_BOUND**

```
private static final int HINT_OPERATION_BOUND
```

---

#### **HINT\_BORDER\_EXTENDER**

```
private static final int HINT_BORDER_EXTENDER
```

---

## HINT\_TILE\_CACHE

```
private static final int HINT_TILE_CACHE
```

---

## KEY\_IMAGE\_LAYOUT

```
public static java.awt.RenderingHints.Key KEY_IMAGE_LAYOUT
```

Key for ImageLayout object values.

---

## KEY\_INTERPOLATION

```
public static java.awt.RenderingHints.Key KEY_INTERPOLATION
```

Key for Interpolation object values.

---

## KEY\_OPERATION\_REGISTRY

```
public static java.awt.RenderingHints.Key KEY_OPERATION_REGISTRY
```

Key for OperationRegistry object values.

---

## KEY\_OPERATION\_BOUND

```
public static java.awt.RenderingHints.Key KEY_OPERATION_BOUND
```

Key for Integer object values representing whether the operation is compute, network, or I/O bound. The values come from the constants `OpImage.OP_COMPUTE_BOUND`, `OpImage.OP_IO_BOUND`, and `OpImage.OP_NETWORK_BOUND`.

---

## KEY\_BORDER\_EXTENDER

```
public static java.awt.RenderingHints.Key KEY_BORDER_EXTENDER
```

Key for BorderExtender object values.

---

## KEY\_TILE\_CACHE

```
public static java.awt.RenderingHints.Key KEY_TILE_CACHE
```

Key for TileCache object values.

---

## operationRegistry

```
private OperationRegistry operationRegistry
```

---

## tileScheduler

```
private TileScheduler tileScheduler
```

---

## tileCache

```
private TileCache tileCache
```

---

## renderingHints

```
private java.awt.RenderingHints renderingHints
```

---

## defaultInstance

```
private static JAI defaultInstance
```

<h2>Constructor Detail</h2>
-----------------------------

## JAI

```
private JAI(OperationRegistry operationRegistry,
            TileScheduler tileScheduler,
            TileCache tileCache,
            java.awt.RenderingHints renderingHints)
```

Returns a new instance of the JAI class.

---

## JAI

```
public JAI()
```

Returns a new instance of the JAI class. The `OperationRegistry`, `TileScheduler`, and `TileCache` will initially be references to those of the default instance. The rendering hints will be set to a clone of those of the default instance.

### Method Detail

#### getDefaultInstance

```
public static JAI getDefaultInstance()
```

Returns the default JAI instance. This instance is used by all of the static methods of this class.

---

#### getOperationRegistry

```
public OperationRegistry getOperationRegistry()
```

Returns the `OperationRegistry` being used by this JAI instance.

---

#### setOperationRegistry

```
public void setOperationRegistry(OperationRegistry operationRegistry)
```

Sets the `OperationRegistry` to be used by this JAI instance.

---

#### getTileScheduler

```
public TileScheduler getTileScheduler()
```

Returns the `TileScheduler` being used by this JAI instance.

---

#### setTileScheduler

```
public void setTileScheduler(TileScheduler tileScheduler)
```

Sets the `TileScheduler` to be used by this JAI instance.

---

#### getTileCache

```
public TileCache getTileCache()
```

Returns the `TileCache` being used by this JAI instance.

---

#### setTileCache

```
public void setTileCache(TileCache tileCache)
```

Sets the `TileCache` to be used by this JAI instance. The `tileCache` parameter will be added to the `RenderingHints` of this JAI instance.

---

#### create

```
public static RenderedOp create(java.lang.String opName,
                               java.awt.image.renderable.ParameterBlock args,
                               java.awt.RenderingHints hints)
```

Creates a `RenderedOp` which represents the named operation, using the source(s) and/or parameter(s) specified in the `ParameterBlock`, and applying the specified hints to the destination. This method should only be used when the final result returned is a single `RenderedImage`.

The default JAI instance is used as the source of the registry and tile scheduler; that is, this method is equivalent to `getDefaultInstance().createNS(opName, args, hints)`. The functionality of this method is the same as its corresponding non-static method `createNS()`.

**Parameters:**

`opName` - The name of the operation.  
`args` - The source(s) and/or parameter(s) for the operation.  
`hints` - The hints for the operation.

**Returns:**

A `RenderedOp` that represents the named operation, or `null` if the specified operation is in the "immediate" mode and the rendering of the `PlanarImage` failed.

**Throws:**

`NullPointerException` - if `opName` is `null`.  
`NullPointerException` - if `args` is `null`.  
`java.lang.IllegalArgumentException` - if no `OperationDescriptor` is registered under the specified operation name in the default operation registry.  
`java.lang.IllegalArgumentException` - if the `OperationDescriptor` registered under the specified operation name in the default operation registry does not support rendered image mode.  
`java.lang.IllegalArgumentException` - if the specified operation does not produce a `java.awt.image.RenderedImage`.  
`java.lang.IllegalArgumentException` - if the specified operation is unable to handle the sources and parameters specified in `args`.

---

## createNS

```
public RenderedOp createNS(java.lang.String opName,  
                           java.awt.image.renderable.ParameterBlock args,  
                           java.awt.RenderingHints hints)
```

Creates a `RenderedOp` which represents the named operation, using the source(s) and/or parameter(s) specified in the `ParameterBlock`, and applying the specified hints to the destination. This method should only be used when the final result returned is a single `RenderedImage`. However, the source(s) supplied may be a collection of rendered images or a collection of collections that at the very basic level include rendered images.

The supplied operation name is validated against the operation registry. The source(s) and/or parameter(s) in the `ParameterBlock` are validated against the named operation's descriptor, both in their numbers and types. Additional restrictions placed on the sources and parameters by an individual operation are also validated by calling its `OperationDescriptor.validateArguments()` method.

JAI allows a parameter to have a `null` input value, if that particular parameter has a default value specified in its operation's descriptor. In this case, the default value will replace the `null` input to be used by its `OpImage`.

JAI also allows unspecified trailing parameters, if these parameters have default values specified in the operation's descriptor. In this case, the default values again are used by the `OpImage`. However, if a parameter, which has a default value, is followed by one or more parameters that have no default values, this parameter must be specified in the `ParameterBlock`, even if it only has a value of `code>null`.

The rendering hints associated with this instance of JAI are overlaid with the hints passed to this method. That is, the set of keys will be the union of the keys from the instance's hints and the hints parameter. If the same key exists in both places, the value from the hints parameter will be used.

This version of `create` is non-static; it may be used with a specific instance of the JAI class. All of the static `create()` methods ultimately call this method, thus inheriting this method's error handling.

Since this method performs parameter checking, it may not be suitable for creating `RenderedOp` nodes meant to be passed to another host using the `RemoteImage` interface. For example, it might be necessary to refer to a file that is present only on the remote host. In such cases, it is possible to instantiate a `RenderedOp` directly, avoiding all checks.

**Parameters:**

`opName` - The name of the operation.  
`args` - The source(s) and/or parameter(s) for the operation.  
`hints` - The hints for the operation.

**Returns:**

A `RenderedOp` that represents the named operation, or `null` if the specified operation is in the "immediate" mode and the rendering of the `PlanarImage` failed.

**Throws:**

`NullPointerException` - if `opName` is `null`.  
`NullPointerException` - if `args` is `null`.  
`java.lang.IllegalArgumentException` - if no `OperationDescriptor` is registered under the specified operation name in the current operation registry.  
`java.lang.IllegalArgumentException` - if the `OperationDescriptor` registered under the specified operation name in the current operation registry does not support rendered image mode.  
`java.lang.IllegalArgumentException` - if the specified operation does not produce a `java.awt.image.RenderedImage`.  
`java.lang.IllegalArgumentException` - if the specified operation is unable to handle the sources and parameters specified

in args.

---

## createCollection

```
public static java.util.Collection createCollection(java.lang.String opName,  
                                                  java.awt.image.renderable.ParameterBlock args,  
                                                  java.awt.RenderingHints hints)
```

Creates a `Collection` which represents the named operation, using the source(s) and/or parameter(s) specified in the `ParameterBlock`, and applying the specified hints to the destination. This method should only be used when the final result returned is a `Collection`. (This includes `javax.media.jai.CollectionOps`.)

The default JAI instance is used as the source of the registry and tile scheduler; that is, this method is equivalent to `getDefaultInstance().createCollectionNS(opName, args, hints)`. The functionality of this method is the same as its corresponding non-static method `createCollectionNS()`.

### Parameters:

`opName` - The name of the operation.  
`args` - The source(s) and/or parameter(s) for the operation.  
`hints` - The hints for the operation.

### Returns:

A `Collection` that represents the named operation.

### Throws:

`NullPointerException` - if `opName` is null.  
`NullPointerException` - if `args` is null.  
`java.lang.IllegalArgumentException` - if no `OperationDescriptor` is registered under the specified operation name in the default operation registry.  
`java.lang.IllegalArgumentException` - if the `OperationDescriptor` registered under the specified operation name in the default operation registry does not support rendered image mode.  
`java.lang.IllegalArgumentException` - if the specified operation does not produce a `java.awt.image.RenderedImage` or a `javax.media.jai.CollectionImage`.  
`java.lang.IllegalArgumentException` - if the specified operation is unable to handle the sources and parameters specified in `args`.

---

## createCollectionNS

```
public java.util.Collection createCollectionNS(java.lang.String opName,  
                                              java.awt.image.renderable.ParameterBlock args,  
                                              java.awt.RenderingHints hints)
```

Creates a `Collection` which represents the named operation, using the source(s) and/or parameter(s) specified in the `ParameterBlock`, and applying the specified hints to the destination. This method should only be used when the final result returned is a `Collection`. (This includes `javax.media.jai.CollectionOps`.) The source(s) supplied may be a collection of rendered images or a collection of collections that at the very basic level include rendered images.

This method should be used to create a `Collection` in the rendered image mode.

The supplied operation name is validated against the operation registry. The source(s) and/or parameter(s) in the `ParameterBlock` are validated against the named operation's descriptor, both in their numbers and types. Additional restrictions placed on the sources and parameters by an individual operation are also validated by calling its `OperationDescriptor.validateArguments()` method.

JAI allows a parameter to have a null input value, if that particular parameter has a default value specified in its operation's descriptor. In this case, the default value will replace the null input to be used by its `OpImage`.

JAI also allows unspecified trailing parameters, if these parameters have default values specified in the operation's descriptor. In this case, the default values again are used by the `OpImage`. However, if a parameter, which has a default value, is followed by one or more parameters that have no default values, this parameter must be specified in the `ParameterBlock`, even if it only has a value of `>null`.

The rendering hints associated with this instance of JAI are overlaid with the hints passed to this method. That is, the set of keys will be the union of the keys from the instance's hints and the hints parameter. If the same key exists in both places, the value from the hints parameter will be used.

This version of `createCollection` is non-static; it may be used with a specific instance of the JAI class.

### Parameters:

`opName` - The name of the operation.  
`args` - The source(s) and/or parameter(s) for the operation.  
`hints` - The hints for the operation.

### Returns:

A `Collection` that represents the named operation.

### Throws:

`NullPointerException` - if `opName` is null.  
`NullPointerException` - if `args` is null.  
`java.lang.IllegalArgumentException` - if no `OperationDescriptor` is registered under the specified operation

name in the current operation registry.  
java.lang.IllegalArgumentException - if the OperationDescriptor registered under the specified operation name in the current operation registry does not support rendered image mode.  
java.lang.IllegalArgumentException - if the specified operation does not produce a  
java.awt.image.RenderedImage or a javax.media.jai.CollectionImage.  
java.lang.IllegalArgumentException - if the specified operation is unable to handle the sources and parameters specified in args.

---

## createTileCache

```
public static TileCache createTileCache(int tileCapacity,  
                                         long memCapacity)
```

Constructs a TileCache with the given tile capacity in tiles and memory capacity in bytes. Users may supply an instance of TileCache to an operation by supplying a RenderingHint with a JAI.KEY\_TILE\_CACHE key and the desired TileCache instance as its value. Note that the absence of a tile cache hint will result in the use of the TileCache belonging to the default JAI instance. To force an operation not to perform caching, a TileCache instance with a tile capacity of 0 may be used. An exception will be thrown if either tileCapacity or memCapacity is negative. Attempting to set either value larger than the JVM size may result in an OutOfMemory exception.

---

## createTileCache

```
public static TileCache createTileCache()
```

Constructs a TileCache with the default tile capacity in tiles and memory capacity in bytes. Users may supply an instance of TileCache to an operation by supplying a RenderingHint with a JAI.KEY\_TILE\_CACHE key and the desired TileCache instance as its value. Note that the absence of a tile cache hint will result in the use of the TileCache belonging to the default JAI instance. To force an operation not to perform caching, a TileCache instance with a tile capacity of 0 may be used.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.renderable.ParameterBlock args)
```

Creates a RenderedOp with null rendering hints.

### Parameters:

opName - The name of the operation.  
args - The source(s) and/or parameter(s) for the operation.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.lang.Object param)
```

Creates a RenderedOp that takes 1 object parameter.

### Parameters:

opName - The name of the operation.  
param - The object parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.lang.Object param1,  
                                java.lang.Object param2)
```

Creates a RenderedOp that takes 2 object parameters.

### Parameters:

opName - The name of the operation.  
param1 - The first object parameter.  
param2 - The second object parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.lang.Object param1,  
                                int param2)
```

Creates a RenderedOp that takes 1 object parameter and 1 int parameter

**Parameters:**

opName - The name of the operation.  
param1 - The object parameter.  
param2 - The int parameter.

---

**create**

```
public static RenderedOp create(java.lang.String opName,  
                               java.lang.Object param1,  
                               java.lang.Object param2,  
                               java.lang.Object param3)
```

Creates a RenderedOp that takes 3 object parameters.

**Parameters:**

opName - The name of the operation.  
param1 - The first object parameter.  
param2 - The second object parameter.  
param3 - The third object parameter.

---

**create**

```
public static RenderedOp create(java.lang.String opName,  
                               int param1,  
                               int param2,  
                               java.lang.Object param3)
```

Creates a RenderedOp that takes 2 int parameters and one object parameter

**Parameters:**

opName - The name of the operation.  
param1 - The first int parameter.  
param2 - The second int parameter.  
param3 - The object parameter.

---

**create**

```
public static RenderedOp create(java.lang.String opName,  
                               java.lang.Object param1,  
                               java.lang.Object param2,  
                               java.lang.Object param3,  
                               java.lang.Object param4)
```

Creates a RenderedOp that takes 4 object parameters.

**Parameters:**

opName - The name of the operation.  
param1 - The first object parameter.  
param2 - The second object parameter.  
param3 - The third object parameter.  
param4 - The fourth object parameter.

---

**create**

```
public static RenderedOp create(java.lang.String opName,  
                               java.lang.Object param1,  
                               int param2,  
                               java.lang.Object param3,  
                               int param4)
```

Creates a RenderedOp that takes 2 object and 2 int parameters.

**Parameters:**

opName - The name of the operation.  
param1 - The first object parameter.  
param2 - The first int parameter.  
param3 - The second object parameter.  
param4 - The second int parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src)
```

Creates a RenderedOp that takes 1 RenderedImage source.

**Parameters:**

opName - The name of the operation.  
src - The RenderedImage src parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.util.Collection srcCol)
```

Creates a RenderedOp that takes 1 Collection source.

**Parameters:**

opName - The name of the operation.  
srcCol - The Collection src parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                java.lang.Object param)
```

Creates a RenderedOp that takes 1 RenderedImage source and 1 object parameter.

**Parameters:**

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param - The object parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                int param)
```

Creates a RenderedOp that takes 1 RenderedImage source and 1 int parameter.

**Parameters:**

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param - The int parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                java.lang.Object param1,  
                                java.lang.Object param2)
```

Creates a RenderedOp that takes 1 RenderedImage source and 2 object parameters.

**Parameters:**

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The first object parameter.  
param2 - The second object parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                java.lang.Object param1,  
                                float param2)
```

Creates a RenderedOp that takes 1 RenderedImage source, 1 object and 1 float parameter.

**Parameters:**

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The object parameter.  
param2 - The float parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                java.lang.Object param1,  
                                java.lang.Object param2,  
                                java.lang.Object param3)
```

Creates a RenderedOp that takes 1 RenderedImage source and 3 object parameters.

### Parameters:

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The first object parameter.  
param2 - The second object parameter.  
param3 - The third object parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                java.lang.Object param1,  
                                int param2,  
                                int param3)
```

Creates a RenderedOp that takes 1 RenderedImage source, 1 object and 2 int parameters.

### Parameters:

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The object parameter.  
param2 - The first int parameter.  
param3 - The second int parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                float param1,  
                                float param2,  
                                java.lang.Object param3)
```

Creates a RenderedOp that takes 1 RenderedImage source, 2 float and 1 object parameters.

### Parameters:

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The first float parameter.  
param2 - The second float parameter.  
param3 - The object parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                java.lang.Object param1,  
                                java.lang.Object param2,  
                                java.lang.Object param3,  
                                java.lang.Object param4)
```

Creates a RenderedOp that takes 1 RenderedImage source and 4 object parameters.

### Parameters:

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The first object parameter.  
param2 - The second object parameter.  
param3 - The third object parameter.  
param4 - The fourth object parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                java.lang.Object param1,  
                                java.lang.Object param2,  
                                int param3,  
                                int param4)
```

Creates a RenderedOp that takes 1 RenderedImage source and 2 object parameters and 2 in parameters

### Parameters:

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The first object parameter.  
param2 - The second object parameter.  
param3 - The first int parameter.  
param4 - The second int parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                int param1,  
                                int param2,  
                                int param3,  
                                int param4)
```

Creates a RenderedOp that takes 1 RenderedImage source and 4 int parameters.

### Parameters:

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The first int parameter.  
param2 - The second int parameter.  
param3 - The third int parameter.  
param4 - The fourth int parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                float param1,  
                                float param2,  
                                float param3,  
                                java.lang.Object param4)
```

Creates a RenderedOp that takes 1 RenderedImage source, 3 float and 1 object parameters.

### Parameters:

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The first float parameter.  
param2 - The second float parameter.  
param3 - The third float parameter.  
param4 - The object parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                java.lang.Object param1,  
                                java.lang.Object param2,  
                                java.lang.Object param3,  
                                java.lang.Object param4,  
                                java.lang.Object param5)
```

Creates a RenderedOp that takes 1 RenderedImage source and 5 object parameters.

### Parameters:

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The first object parameter.  
param2 - The second object parameter.  
param3 - The third object parameter.  
param4 - The fourth object parameter.  
param5 - The fifth object parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                float param1,  
                                float param2,  
                                float param3,  
                                float param4,  
                                java.lang.Object param5)
```

Creates a RenderedOp that takes 1 RenderedImage source, 4 float parameters and one object parameter.

### Parameters:

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The first float parameter.  
param2 - The second float parameter.  
param3 - The third float parameter.  
param4 - The fourth float parameter.  
param5 - The object parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                float param1,  
                                int param2,  
                                float param3,  
                                float param4,  
                                java.lang.Object param5)
```

Creates a RenderedOp that takes 1 RenderedImage source, 3 float parameters, 1 int parameter and 1 object parameter.

### Parameters:

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The first float parameter.  
param2 - The int parameter.  
param3 - The second float parameter.  
param4 - The third float parameter.  
param5 - The object parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                java.lang.Object param1,  
                                java.lang.Object param2,  
                                java.lang.Object param3,  
                                java.lang.Object param4,  
                                java.lang.Object param5,  
                                java.lang.Object param6)
```

Creates a RenderedOp that takes 1 RenderedImage source and 6 object parameters.

### Parameters:

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The first object parameter.  
param2 - The second object parameter.  
param3 - The third object parameter.  
param4 - The fourth object parameter.  
param5 - The fifth object parameter.  
param6 - The sixth object parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,  
                                java.awt.image.RenderedImage src,  
                                int param1,  
                                int param2,
```

```
int param3,
int param4,
int param5,
java.lang.Object param6)
```

Creates a RenderedOp that takes 1 RenderedImage source, 5 int parameters and 1 object parameter.

**Parameters:**

opName - The name of the operation.  
src - The RenderedImage src parameter.  
param1 - The first int parameter.  
param2 - The second int parameter.  
param3 - The third int parameter.  
param4 - The fourth int parameter.  
param5 - The fifth int parameter.  
param6 - The object parameter.

---

## create

```
public static RenderedOp create(java.lang.String opName,
                               java.awt.image.RenderedImage src1,
                               java.awt.image.RenderedImage src2)
```

Creates a RenderedOp that takes 2 RenderedImage sources.

**Parameters:**

opName - The name of the operation.  
src1 - The first RenderedImage src.  
src2 - The second RenderedImage src.

---

## create

```
public static RenderedOp create(java.lang.String opName,
                               java.awt.image.RenderedImage src1,
                               java.awt.image.RenderedImage src2,
                               java.lang.Object param1,
                               java.lang.Object param2,
                               java.lang.Object param3,
                               java.lang.Object param4)
```

Creates a RenderedOp that takes 2 RenderedImage sources and 4 object parameters.

**Parameters:**

opName - The name of the operation.  
src1 - The first RenderedImage src.  
src2 - The second RenderedImage src.  
param1 - The first object parameter.  
param2 - The second object parameter.  
param3 - The third object parameter.  
param4 - The fourth object parameter.

---

## createCollection

```
public static java.util.Collection createCollection(java.lang.String opName,
                                                    java.awt.image.renderable.ParameterBlock args)
```

Creates a Collection with null rendering hints.

**Parameters:**

opName - The name of the operation.  
args - The source(s) and/or parameter(s) for the operation.

---

## createRenderable

```
public static RenderableOp createRenderable(java.lang.String opName,
                                             java.awt.image.renderable.ParameterBlock args)
```

Creates a RenderableOp that represents the named operation, using the source(s) and/or parameter(s) specified in the ParameterBlock. This method should only be used when the final result returned is a single RenderableImage.

The default JAI instance is used as the source of the registry and tile scheduler; that is, this method is equivalent to `getDefaultInstance().createRenderableNS(opName, args)`. The functionality of this method is the same as its corresponding non-static method `createRenderableNS()`.

**Parameters:**

opName - The name of the operation.  
args - The source(s) and/or parameter(s) for the operation.

---

**Returns:**

A `RenderableOp` that represents the named operation.

**Throws:**

`NullPointerException` - if `opName` is null.

`NullPointerException` - if `args` is null.

`java.lang.IllegalArgumentException` - if no `OperationDescriptor` is registered under the specified operation name in the default operation registry.

`java.lang.IllegalArgumentException` - if the `OperationDescriptor` registered under the specified operation name in the default operation registry does not support renderable image mode.

`java.lang.IllegalArgumentException` - if the specified operation does not produce a

`java.awt.image.renderable.RenderableImage`.

`java.lang.IllegalArgumentException` - if the specified operation is unable to handle the sources and parameters specified in `args`.

## createRenderableNS

```
public RenderableOp createRenderableNS(java.lang.String opName,
                                       java.awt.image.renderable.ParameterBlock args)
```

Creates a `RenderableOp` that represents the named operation, using the source(s) and/or parameter(s) specified in the `ParameterBlock`. This method should only be used when the final result returned is a single `RenderableImage`. However, the source(s) supplied may be a collection of renderable images or a collection of collections that at the very basic level include renderable images.

The supplied operation name is validated against the operation registry. The source(s) and/or parameter(s) in the `ParameterBlock` are validated against the named operation's descriptor, both in their numbers and types. Additional restrictions placed on the sources and parameters by an individual operation are also validated by calling its `OperationDescriptor.validateRenderableArguments()` method.

JAI allows a parameter to have a null input value, if that particular parameter has a default value specified in its operation's descriptor. In this case, the default value will replace the null input to be used by its `OpImage`.

JAI also allows unspecified trailing parameters, if these parameters have default values specified in the operation's descriptor. In this case, the default values again are used by the `OpImage`. However, if a parameter, which has a default value, is followed by one or more parameters that have no default values, this parameter must be specified in the `ParameterBlock`, even if it only has a value of code>null.

This version of the "createRenderable" is non-static; it may be used with a specific instance of the JAI class.

**Parameters:**

`opName` - The name of the operation.

`args` - The source(s) and/or parameter(s) for the operation.

**Returns:**

A `RenderableOp` that represents the named operation.

**Throws:**

`NullPointerException` - if `opName` is null.

`NullPointerException` - if `args` is null.

`java.lang.IllegalArgumentException` - if no `OperationDescriptor` is registered under the specified operation name in the current operation registry.

`java.lang.IllegalArgumentException` - if the `OperationDescriptor` registered under the specified operation name in the current operation registry does not support renderable image mode.

`java.lang.IllegalArgumentException` - if the specified operation does not produce a

`java.awt.image.renderable.RenderableImage`.

`java.lang.IllegalArgumentException` - if the specified operation is unable to handle the sources and parameters specified in `args`.

## createRenderableCollection

```
public static java.util.Collection createRenderableCollection(java.lang.String opName,
                                                             java.awt.image.renderable.ParameterBlock args)
```

Creates a `Collection` which represents the named operation, using the source(s) and/or parameter(s) specified in the `ParameterBlock`. This method should only be used when the final result returned is a `Collection`. (This includes `javax.media.jai.CollectionOps`.)

The default JAI instance is used as the source of the registry and tile scheduler; that is, this method is equivalent to `getDefaultInstance().createRenderableCollectionNS(opName, args)`. The functionality of this method is the same as its corresponding non-static method `createRenderableCollectionNS()`.

**Parameters:**

`opName` - The name of the operation.

`args` - The source(s) and/or parameter(s) for the operation.

**Returns:**

A Collection that represents the named operation.

**Throws:**

NullPointerException - if opName is null.

NullPointerException - if args is null.

java.lang.IllegalArgumentException - if no OperationDescriptor is registered under the specified operation name in the default operation registry.

java.lang.IllegalArgumentException - if the OperationDescriptor registered under the specified operation name in the default operation registry does not support renderable image mode.

java.lang.IllegalArgumentException - if the specified operation does not produce a

java.awt.image.renderable.RenderableImage or a javax.media.jai.CollectionImage.

java.lang.IllegalArgumentException - if the specified operation is unable to handle the sources and parameters specified in args.

**createRenderableCollectionNS**

```
public java.util.Collection createRenderableCollectionNS(java.lang.String opName,
                                                         java.awt.image.renderable.ParameterBlock args)
```

Creates a Collection which represents the named operation, using the source(s) and/or parameter(s) specified in the ParameterBlock. This method should only be used when the final result returned is a Collection. (This includes javax.media.jai.CollectionOps.) The source(s) supplied may be a collection of renderable images or a collection of collections that at the very basic level include renderable images.

This method should be used to create a Collection in the renderable image mode.

The supplied operation name is validated against the operation registry. The source(s) and/or parameter(s) in the ParameterBlock are validated against the named operation's descriptor, both in their numbers and types. Additional restrictions placed on the sources and parameters by an individual operation are also validated by calling its OperationDescriptor.validateRenderableArguments() method.

JAI allows a parameter to have a null input value, if that particular parameter has a default value specified in its operation's descriptor. In this case, the default value will replace the null input to be used by its OpImage.

JAI also allows unspecified trailing parameters, if these parameters have default values specified in the operation's descriptor. In this case, the default values again are used by the OpImage. However, if a parameter, which has a default value, is followed by one or more parameters that have no default values, this parameter must be specified in the ParameterBlock, even if it only has a value of code>null.

This version of createRenderableCollection is non-static; it may be used with a specific instance of the JAI class.

**Parameters:**

opName - The name of the operation.

args - The source(s) and/or parameter(s) for the operation.

**Returns:**

A Collection that represents the named operation.

**Throws:**

NullPointerException - if opName is null.

NullPointerException - if args is null.

java.lang.IllegalArgumentException - if no OperationDescriptor is registered under the specified operation name in the current operation registry.

java.lang.IllegalArgumentException - if the OperationDescriptor registered under the specified operation name in the current operation registry does not support renderable image mode.

java.lang.IllegalArgumentException - if the specified operation does not produce a

java.awt.image.renderable.RenderableImage or a javax.media.jai.CollectionImage.

java.lang.IllegalArgumentException - if the specified operation is unable to handle the sources and parameters specified in args.

**getRenderingHints**

```
public java.awt.RenderingHints getRenderingHints()
```

Returns the RenderingHints associated with this JAI instance. These rendering hints will be merged with any hints supplied as an argument to the createNS() method.

**setRenderingHints**

```
public void setRenderingHints(java.awt.RenderingHints hints)
```

Sets the RenderingHints associated with this JAI instance. These rendering hints will be merged with any hints supplied as an argument to the createNS() method.

The `hints` argument must be non-null, otherwise a `NullPointerException` will be thrown.

---

### **clearRenderingHints**

```
public void clearRenderingHints()
```

Clears the `RenderingHints` associated with this JAI instance.

---

### **getRenderingHint**

```
public java.lang.Object getRenderingHint(java.awt.RenderingHints.Key key)
```

Returns the hint value associated with a given key in this JAI instance, or null if no value is associated with the given key.

**Throws:**

`java.lang.IllegalArgumentException` - if key is null.

---

### **setRenderingHint**

```
public void setRenderingHint(java.awt.RenderingHints.Key key,  
                             java.lang.Object value)
```

Sets the hint value associated with a given key in this JAI instance.

**Throws:**

`java.lang.IllegalArgumentException` - if key is null.

`java.lang.IllegalArgumentException` - if value is null.

`java.lang.IllegalArgumentException` - if value is not of the correct type for the given hint.

---

### **removeRenderingHint**

```
public void removeRenderingHint(java.awt.RenderingHints.Key key)
```

Removes the hint value associated with a given key in this JAI instance.

---

## javax.media.jai Class KernelJAI

java.lang.Object  
|  
+-- javax.media.jai.KernelJAI

---

public class **KernelJAI**  
extends java.lang.Object  
implements java.io.Serializable

A kernel, used by the Convolve, Ordered Dither, and Error Diffusion operations.

This class is used as an auxiliary class to perform a Convolve, Ordered Dither, or Error Diffusion operation on an image. In the latter two operations the kernel is referred to as a "dither mask" or "error filter", respectively, rather than as a kernel.

A KernelJAI is characterized by its width, height, and origin, or key element. The key element is the element which is placed over the current source pixel to perform convolution or error diffusion. In the case of ordered dithering an array of KernelJAI objects is actually required with there being one KernelJAI per band of the image to be dithered. For ordered dithering the location of the key element is in fact irrelevant.

### See Also:

ConvolveDescriptor, OrderedDitherDescriptor, ErrorDiffusionDescriptor

---

## Field Detail

### ERROR\_FILTER\_FLOYD\_STEINBERG

public static final KernelJAI **ERROR\_FILTER\_FLOYD\_STEINBERG**

Floyd and Steinberg error filter (1975).

(1/16 x)    [    \* 7 ]  
             [ 3 5 1 ]

---

### ERROR\_FILTER\_JARVIS

public static final KernelJAI **ERROR\_FILTER\_JARVIS**

Jarvis, Judice, and Ninke error filter (1976).

(1/48 x)    [    \* 7 5 ]  
             [ 3 5 7 5 3 ]  
             [ 1 3 5 3 1 ]

---

### ERROR\_FILTER\_STUCKI

public static final KernelJAI **ERROR\_FILTER\_STUCKI**

Stucki error filter (1981).

(1/42 x)    [    \* 7 5 ]  
             [ 2 4 8 4 2 ]  
             [ 1 2 4 2 1 ]

---

### DITHER\_MASK\_441

public static final KernelJAI[] **DITHER\_MASK\_441**

4x4x1 mask useful for dithering 8-bit grayscale images to 1-bit images.

---

### DITHER\_MASK\_443

public static final KernelJAI[] **DITHER\_MASK\_443**

4x4x3 mask useful for dithering 24-bit color images to 8-bit pseudocolor images.

---

## GRADIENT\_MASK\_SOBEL\_HORIZONTAL

public static final KernelJAI **GRADIENT\_MASK\_SOBEL\_HORIZONTAL**  
Gradient Mask for SOBEL\_HORIZONTAL

---

## GRADIENT\_MASK\_SOBEL\_VERTICAL

public static final KernelJAI **GRADIENT\_MASK\_SOBEL\_VERTICAL**  
Gradient Mask for SOBEL\_VERTICAL

---

### width

protected int **width**  
The width of the kernel.

---

### height

protected int **height**  
The height of the kernel.

---

### xOrigin

protected int **xOrigin**  
The X coordinate of the key element.

---

### yOrigin

protected int **yOrigin**  
The Y coordinate of the key element.

---

### data

protected float[] **data**  
The kernel data in row-major format.

---

### dataH

protected float[] **dataH**  
The horizontal data for a separable kernel

---

### dataV

protected float[] **dataV**  
The vertical data for a separable kernel

---

### isSeparable

protected boolean **isSeparable**  
True if the kernel is separable.

---

### isHorizontallySymmetric

protected boolean **isHorizontallySymmetric**  
True if the kernel has horizontal (Y axis) symmetry.

---

## isVerticallySymmetric

protected boolean **isVerticallySymmetric**  
True if the kernel has vertical (X axis) symmetry.

---

## rotatedKernel

protected KernelJAI **rotatedKernel**  
Variable to cache a copy of the rotated kernel

---

## FLOAT\_ZERO\_TOL

public static final float **FLOAT\_ZERO\_TOL**

### Constructor Detail

#### KernelJAI

```
public KernelJAI(int width,  
                 int height,  
                 int xOrigin,  
                 int yOrigin,  
                 float[] data)
```

Constructs a KernelJAI with the given parameters. The data array is copied.

**Parameters:**

width - the width of the kernel.  
height - the height of the kernel.  
xOrigin - the X coordinate of the key kernel element.  
yOrigin - the Y coordinate of the key kernel element.  
data - the float data in row-major format.

**Throws:**

NullPointerException - if data is null.  
java.lang.IllegalArgumentException - if width is not a positive number.  
java.lang.IllegalArgumentException - if height is not a positive number.  
java.lang.IllegalArgumentException - if kernel data array does not have width \* height number of elements.

---

#### KernelJAI

```
public KernelJAI(int width,  
                 int height,  
                 int xOrigin,  
                 int yOrigin,  
                 float[] dataH,  
                 float[] dataV)
```

Constructs a separable KernelJAI from two float arrays. The data arrays are copied.

**Parameters:**

width - the width of the kernel.  
height - the height of the kernel.  
xOrigin - the X coordinate of the key kernel element.  
yOrigin - the Y coordinate of the key kernel element.  
dataH - the float data for the horizontal direction.  
dataV - the float data for the vertical direction.

**Throws:**

NullPointerException - if dataH is null.  
NullPointerException - if dataV is null.  
java.lang.IllegalArgumentException - if width is not a positive number.  
java.lang.IllegalArgumentException - if height is not a positive number.  
java.lang.IllegalArgumentException - if dataH does not have width elements.  
java.lang.IllegalArgumentException - if dataV does not have height elements.

---

## KernelJAI

```
public KernelJAI(int width,  
                 int height,  
                 float[] data)
```

Constructs a kernel with the given parameters. The data array is copied. The key element is set to (trunc(width/2), trunc(height/2)).

### Parameters:

width - the width of the kernel.  
height - the height of the kernel.  
data - the float data in row-major format.

### Throws:

NullPointerException - if data is null.  
java.lang.IllegalArgumentException - if width is not a positive number.  
java.lang.IllegalArgumentException - if height is not a positive number.  
java.lang.IllegalArgumentException - if data does not have width \* height number of elements.

---

## KernelJAI

```
public KernelJAI(java.awt.image.Kernel k)
```

Constructs a KernelJAI from a java.awt.image.Kernel object.

### Throws:

NullPointerException - if k is null.

---

## Method Detail

### checkSeparable

```
private void checkSeparable()
```

---

### classifyKernel

```
private void classifyKernel()
```

---

### getWidth

```
public int getWidth()
```

Returns the width of the kernel.

---

### getHeight

```
public int getHeight()
```

Returns the height of the kernel.

---

### getXOrigin

```
public int getXOrigin()
```

Returns the X coordinate of the key kernel element.

---

### getYOrigin

```
public int getYOrigin()
```

Returns the Y coordinate of the key kernel element.

---

### getKernelData

```
public float[] getKernelData()
```

Returns a copy of the kernel data in row-major format.

---

### **getHorizontalKernelData**

public float[] **getHorizontalKernelData**()

Returns the horizontal portion of the kernel if the kernel is separable, or null otherwise. The kernel may be tested for separability by calling `isSeparable()`.

---

### **getVerticalKernelData**

public float[] **getVerticalKernelData**()

Returns the vertical portion of the kernel if the kernel is separable, or null otherwise. The kernel may be tested for separability by calling `isSeparable()`.

---

### **getElement**

public float **getElement**(int xIndex,  
int yIndex)

Returns a given element of the kernel.

**Throws:**

ArrayIndexOutOfBoundsException - if either xIndex or yIndex is an invalid index.

---

### **isSeparable**

public boolean **isSeparable**()

Returns true if the kernel is separable. NOTE: when separable, there will be two valid vectors

---

### **isHorizontallySymmetric**

public boolean **isHorizontallySymmetric**()

Returns true if the kernel has horizontal (Y axis) symmetry.

---

### **isVerticallySymmetric**

public boolean **isVerticallySymmetric**()

Returns true if the kernel has vertical (X axis) symmetry.

---

### **getLeftPadding**

public int **getLeftPadding**()

Returns the number of pixels required to the left of the key element.

---

### **getRightPadding**

public int **getRightPadding**()

Returns the number of pixels required to the right of the key element.

---

### **getTopPadding**

public int **getTopPadding**()

Returns the number of pixels required above the key element.

---

### **getBottomPadding**

public int **getBottomPadding**()

Returns the number of pixels required below the key element.

---

## **fAbs**

```
private static final float fAbs(float a)
```

Computing the absolute value of a float type

---

## **getRotatedKernel**

```
public KernelJAI getRotatedKernel()
```

Returns a 180 degree rotated version of the kernel. This is needed by most convolve operations to get the correct results.  
modification on 9/20: make it work for separable kernels. -jxz

**Returns:**

the rotated kernel.

---

## javax.media.jai Class LookupTableJAI

```
java.lang.Object
|
+-- javax.media.jai.LookupTableJAI
```

**Direct Known Subclasses:**  
ColorCube

---

```
public class LookupTableJAI
extends java.lang.Object
implements java.io.Serializable
```

A lookup table object associated with the "Lookup" operation. The "Lookup" operation is described in `javax.media.jai.operator.LookupDescriptor`.

This object represents a single- or multi-banded table of any JAI supported data types. A single- or multi-banded source image of integral data types is passed through the table and transformed into a single- or multi-banded destination image of both integral and float or double data types.

The table data may cover only a subrange of the legal range of the input data type. The subrange is selected by means of an offset parameter which is to be subtracted from the input value before indexing into the table array. When only a subranged table is used with a source image, it is up to the user to make certain that the source image does not have pixel values outside of the table range. Other wise, the result is undefined, with possible outcomes being an `ArrayIndexOutOfBoundsException`, segmentation fault, or random results.

The table data is saved by reference only.

**See Also:**  
`LookupDescriptor`

---

### Field Detail

#### data

```
transient java.awt.image.DataBuffer data
```

The table data.

### Constructor Detail

#### LookupTableJAI

```
public LookupTableJAI(byte[] data)
```

Constructs a single-banded byte lookup table. The index offset is 0.

**Parameters:**  
data - The single-banded byte data.

**Throws:**  
`NullPointerException` - if data is null.

---

#### LookupTableJAI

```
public LookupTableJAI(byte[] data,
                      int offset)
```

Constructs a single-banded byte lookup table with an index offset.

**Parameters:**  
data - The single-banded byte data.  
offset - The offset.

**Throws:**  
`NullPointerException` - if data is null.

---

## LookupTableJAI

public **LookupTableJAI**(byte[][] data)

Constructs a multi-banded byte lookup table. The index offset for each band is 0.

**Parameters:**

data - The multi-banded byte data in [band][index] format.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

public **LookupTableJAI**(byte[][] data,  
int offset)

Constructs a multi-banded byte lookup table where all bands have the same index offset.

**Parameters:**

data - The multi-banded byte data in [band][index] format.

offset - The common offset for all bands.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

public **LookupTableJAI**(byte[][] data,  
int[] offsets)

Constructs a multi-banded byte lookup table where each band has a different index offset.

**Parameters:**

data - The multi-banded byte data in [band][index] format.

offsets - The offsets for the bands.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

public **LookupTableJAI**(short[] data,  
boolean isUShort)

Constructs a single-banded short or unsigned short lookup table. The index offset is 0.

**Parameters:**

data - The single-banded short data.

isUShort - True if data type is `DataBuffer.TYPE_USHORT`; false if data type is `DataBuffer.TYPE_SHORT`.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

public **LookupTableJAI**(short[] data,  
int offset,  
boolean isUShort)

Constructs a single-banded short or unsigned short lookup table with an index offset.

**Parameters:**

data - The single-banded short data.

offset - The offset.

isUShort - True if data type is `DataBuffer.TYPE_USHORT`; false if data type is `DataBuffer.TYPE_SHORT`.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

public **LookupTableJAI**(short[][] data,  
boolean isUShort)

Constructs a multi-banded short or unsigned short lookup table. The index offset for each band is 0.

**Parameters:**

data - The multi-banded short data in [band][index] format.

isUShort - True if data type is `DataBuffer.TYPE_USHORT`; false if data type is `DataBuffer.TYPE_SHORT`.

**Throws:**  
NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(short[][] data,  
                      int offset,  
                      boolean isUShort)
```

Constructs a multi-banded short or unsigned short lookup table where all bands have the same index offset.

**Parameters:**  
data - The multi-banded short data in [band][index] format.  
offset - The common offset for all bands.  
isUShort - True if data type is `DataBuffer.TYPE_USHORT`; false if data type is `DataBuffer.TYPE_SHORT`.

**Throws:**  
NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(short[][] data,  
                      int[] offsets,  
                      boolean isUShort)
```

Constructs a multi-banded short or unsigned short lookup table where each band has a different index offset.

**Parameters:**  
data - The multi-banded short data in [band][index] format.  
offsets - The offsets for the bands.  
isUShort - True if data type is `DataBuffer.TYPE_USHORT`; false if data type is `DataBuffer.TYPE_SHORT`.

**Throws:**  
NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(int[] data)
```

Constructs a single-banded int lookup table. The index offset is 0.

**Parameters:**  
data - The single-banded int data.

**Throws:**  
NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(int[] data,  
                      int offset)
```

Constructs a single-banded int lookup table with an index offset.

**Parameters:**  
data - The single-banded int data.  
offset - The offset.

**Throws:**  
NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(int[][] data)
```

Constructs a multi-banded int lookup table. The index offset for each band is 0.

**Parameters:**  
data - The multi-banded int data in [band][index] format.

**Throws:**  
NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(int[][] data,  
                      int offset)
```

Constructs a multi-banded int lookup table where all bands have the same index offset.

**Parameters:**

data - The multi-banded int data in [band][index] format.  
offset - The common offset for all bands.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(int[][] data,  
                      int[] offsets)
```

Constructs a multi-banded int lookup table where each band has a different index offset.

**Parameters:**

data - The multi-banded int data in [band][index] format.  
offsets - The offsets for the bands.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(float[] data)
```

Constructs a single-banded float lookup table. The index offset is 0.

**Parameters:**

data - The single-banded float data.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(float[] data,  
                      int offset)
```

Constructs a single-banded float lookup table with an index offset.

**Parameters:**

data - The single-banded float data.  
offset - The offset.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(float[][] data)
```

Constructs a multi-banded float lookup table. The index offset for each band is 0.

**Parameters:**

data - The multi-banded float data in [band][index] format.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(float[][] data,  
                      int offset)
```

Constructs a multi-banded float lookup table where all bands have the same index offset.

**Parameters:**

data - The multi-banded float data in [band][index] format.  
offset - The common offset for all bands.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(float[][] data,  
                      int[] offsets)
```

Constructs a multi-banded float lookup table where each band has a different index offset.

**Parameters:**

data - The multi-banded float data in [band][index] format.  
offsets - The offsets for the bands.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(double[] data)
```

Constructs a single-banded double lookup table. The index offset is 0.

**Parameters:**

data - The single-banded double data.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(double[] data,  
                      int offset)
```

Constructs a single-banded double lookup table with an index offset.

**Parameters:**

data - The single-banded double data.  
offset - The offset.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(double[][] data)
```

Constructs a multi-banded double lookup table. The index offset for each band is 0.

**Parameters:**

data - The multi-banded double data in [band][index] format.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(double[][] data,  
                      int offset)
```

Constructs a multi-banded double lookup table where all bands have the same index offset.

**Parameters:**

data - The multi-banded double data in [band][index] format.  
offset - The common offset for all bands.

**Throws:**

NullPointerException - if data is null.

---

## LookupTableJAI

```
public LookupTableJAI(double[][] data,  
                      int[] offsets)
```

Constructs a multi-banded double lookup table where each band has a different index offset.

**Parameters:**

data - The multi-banded double data in [band][index] format.  
offsets - The offsets for the bands.

**Throws:**

NullPointerException - if data is null.

<h2>Method Detail</h2>
------------------------

## **getData**

```
public java.awt.image.DataBuffer getData()
```

Returns the table data as a DataBuffer.

---

## **getByteData**

```
public byte[][] getByteData()
```

Returns the byte table data in array format, or null if the table's data type is not byte.

---

## **getByteData**

```
public byte[] getByteData(int band)
```

Returns the byte table data of a specific band in array format, or null if the table's data type is not byte.

---

## **getShortData**

```
public short[][] getShortData()
```

Returns the short table data in array format, or null if the table's data type is not short. This includes both signed and unsigned short table data.

---

## **getShortData**

```
public short[] getShortData(int band)
```

Returns the short table data of a specific band in array format, or null if the table's data type is not short.

---

## **getIntData**

```
public int[][] getIntData()
```

Returns the integer table data in array format, or null if the table's data type is not int.

---

## **getIntData**

```
public int[] getIntData(int band)
```

Returns the integer table data of a specific band in array format, or null if table's data type is not int.

---

## **getFloatData**

```
public float[][] getFloatData()
```

Returns the float table data in array format, or null if the table's data type is not float.

---

## **getFloatData**

```
public float[] getFloatData(int band)
```

Returns the float table data of a specific band in array format, or null if table's data type is not float.

---

## **getDoubleData**

```
public double[][] getDoubleData()
```

Returns the double table data in array format, or null if the table's data type is not double.

---

## **getDoubleData**

```
public double[] getDoubleData(int band)
```

Returns the double table data of a specific band in array format, or null if table's data type is not double.

---

## getOffsets

```
public int[] getOffsets()
```

Returns the index offsets of entry 0 for all bands.

---

## getOffset

```
public int getOffset()
```

Returns the index offset of entry 0 for the default band.

---

## getOffset

```
public int getOffset(int band)
```

Returns the index offset of entry 0 for a specific band.

---

## getNumBands

```
public int getNumBands()
```

Returns the number of bands of the table.

---

## getNumEntries

```
public int getNumEntries()
```

Returns the number of entries per band of the table.

---

## getDataType

```
public int getDataType()
```

Returns the data type of the table data.

---

## getDestNumBands

```
public int getDestNumBands(int srcNumBands)
```

Returns the number of bands of the destination image, based on the number of bands of the source image and lookup table.

**Parameters:**

srcNumBands - The number of bands of the source image.

**Returns:**

the number of bands in destination image.

---

## getDestSampleModel

```
public java.awt.image.SampleModel getDestSampleModel(java.awt.image.SampleModel srcSampleModel)
```

Returns a SampleModel suitable for holding the output of a lookup operation on the source data described by a given SampleModel with this table. The width and height of the destination SampleModel are the same as that of the source. This method will return null if the source SampleModel has a non-integral data type.

**Parameters:**

srcSampleModel - The SampleModel of the source image.

**Returns:**

sampleModel suitable for the destination image.

**Throws:**

NullPointerException - if srcSampleModel is null.

---

## getDestSampleModel

```
public java.awt.image.SampleModel getDestSampleModel(java.awt.image.SampleModel srcSampleModel,
                                                    int width,
                                                    int height)
```

Returns a SampleModel suitable for holding the output of a lookup operation on the source data described by a given SampleModel with this table. This method will return null if the source SampleModel has a non-integral data type.

**Parameters:**

srcSampleModel - The SampleModel of the source image.

width - The width of the destination SampleModel.

height - The height of the destination SampleModel.  
**Returns:**  
sampleModel suitable for the destination image.  
**Throws:**  
NullPointerException - if srcSampleModel is null.

---

## isIntegralDataType

public boolean **isIntegralDataType**(java.awt.image.SampleModel sampleModel)  
Validates data type. Returns true if it's one of the integral data types; false otherwise.  
**Throws:**  
NullPointerException - if sampleModel is null.

---

## isIntegralDataType

public boolean **isIntegralDataType**(int dataType)  
Returns true if the specified data type is an integral data type, such as byte, ushort, short, or int.

---

## lookup

public int **lookup**(int band,  
                    int value)  
Performs lookup on a given value belonging to a given source band, and returns the result as an int.  
**Parameters:**  
band - The source band the value is from.  
value - The source value to be placed through the lookup table.

---

## lookupFloat

public float **lookupFloat**(int band,  
                            int value)  
Performs lookup on a given value belonging to a given source band, and returns the result as a float.  
**Parameters:**  
band - The source band the value is from.  
value - The source value to be placed through the lookup table.

---

## lookupDouble

public double **lookupDouble**(int band,  
                              int value)  
Performs lookup on a given value belonging to a given source band, and returns the result as a double.  
**Parameters:**  
band - The source band the value is from.  
value - The source value to be placed through the lookup table.

---

## lookup

public java.awt.image.WritableRaster **lookup**(java.awt.image.WritableRaster src)  
Performs table lookup in place on a given WritableRaster. The The lookup operation must preserve the data type and SampleModel of the source. A reference to the supplied WritableRaster will be returned.  
**Throws:**  
NullPointerException - if the source is null.  
java.lang.IllegalArgumentException - if the source's SampleModel is not of integral type.  
java.lang.IllegalArgumentException - if the lookup operation would result in a change in the data type or number of bands of the Raster.

---

## lookup

public java.awt.image.WritableRaster **lookup**(java.awt.image.Raster src,  
  java.awt.image.WritableRaster dst,  
  java.awt.Rectangle rect)

Performs table lookup on a source Raster, writing the result into a supplied WritableRaster. The destination must have a data type and SampleModel appropriate to the results of the lookup operation. The table lookup operation is performed within a specified rectangle.

The `dst` argument may be null, in which case a new WritableRaster is created using the appropriate SampleModel.

The rectangle of interest may be null, in which case the operation will be performed on the intersection of the source and destination bounding rectangles.

**Parameters:**

`src` - A Raster containing the source pixel data.

`dst` - The WritableRaster to be computed, or null. If supplied, its data type and number of bands must be suitable for the source and lookup table.

`rect` - The rectangle within the tile to be computed. If `rect` is null, the intersection of the source and destination bounds will be used. Otherwise, it will be clipped to the intersection of the source and destination bounds.

**Returns:**

A reference to the supplied WritableRaster, or to a new WritableRaster if the supplied one was null.

**Throws:**

`java.lang.IllegalArgumentException` - if the source is null.

`java.lang.IllegalArgumentException` - if the source's SampleModel is not of integral type.

`java.lang.IllegalArgumentException` - if the destination's data type or number of bands differ from those returned by `getDataType()` and `getNumBands()`.

---

## lookup

```
private void lookup(int srcLineStride,
                   int srcPixelStride,
                   int[] srcBandOffsets,
                   byte[][] srcData,
                   int width,
                   int height,
                   int bands,
                   int dstLineStride,
                   int dstPixelStride,
                   int[] dstBandOffsets,
                   byte[][] dstData,
                   int[] tblOffsets,
                   byte[][] tblData)
```

---

## lookupU

```
private void lookupU(int srcLineStride,
                    int srcPixelStride,
                    int[] srcBandOffsets,
                    short[][] srcData,
                    int width,
                    int height,
                    int bands,
                    int dstLineStride,
                    int dstPixelStride,
                    int[] dstBandOffsets,
                    byte[][] dstData,
                    int[] tblOffsets,
                    byte[][] tblData)
```

---

## lookup

```
private void lookup(int srcLineStride,
                   int srcPixelStride,
                   int[] srcBandOffsets,
                   short[][] srcData,
                   int width,
                   int height,
                   int bands,
                   int dstLineStride,
                   int dstPixelStride,
                   int[] dstBandOffsets,
                   byte[][] dstData,
                   int[] tblOffsets,
                   byte[][] tblData)
```

---

## lookup

```
private void lookup(int srcLineStride,
                    int srcPixelStride,
                    int[] srcBandOffsets,
                    int[][] srcData,
                    int width,
                    int height,
                    int bands,
                    int dstLineStride,
                    int dstPixelStride,
                    int[] dstBandOffsets,
                    byte[][] dstData,
                    int[] tblOffsets,
                    byte[][] tblData)
```

                  int dstPixelStride,
                  int[] dstBandOffsets,
                  double[][] dstData,
                  int[] tblOffsets,
                  double[][] tblData)

```

---

## lookup

```

private void lookup(int srcLineStride,
                  int srcPixelStride,
                  int[] srcBandOffsets,
                  int[][] srcData,
                  int width,
                  int height,
                  int bands,
                  int dstLineStride,
                  int dstPixelStride,
                  int[] dstBandOffsets,
                  double[][] dstData,
                  int[] tblOffsets,
                  double[][] tblData)

```

---

## findNearestEntry

```

public int findNearestEntry(float[] pixel)

```

Determine which entry in the LookupTableJAI is closest in Euclidean distance to the argument pixel.

**Parameters:**

pixel - the pixel the closest entry to which is to be found.

**Returns:**

the index of the closest entry. If the data array of the lookup table is in the format data[numBands][numEntries], then the value *v* for band *b* of the closest entry is

*v* = data[*b*][index - lookup.getOffset()]

where *index* is the returned value of this method.

**Throws:**

NullPointerException - if pixel is null.

---

## **writeObject**

```
private void writeObject(java.io.ObjectOutputStream out)  
    throws java.io.IOException
```

Serialize the LookupTableJAI.

**Parameters:**

out - The ObjectOutputStream.

---

## **readObject**

```
private void readObject(java.io.ObjectInputStream in)  
    throws java.io.IOException,  
           java.lang.ClassNotFoundException
```

Deserialize the LookupTableJAI.

**Parameters:**

in - The ObjectInputStream.

---

## javax.media.jai Class MultiResolutionRenderableImage

java.lang.Object  
|  
+-- javax.media.jai.MultiResolutionRenderableImage

---

public class **MultiResolutionRenderableImage**  
extends java.lang.Object  
implements java.awt.image.renderable.RenderableImage, java.io.Serializable  
A RenderableImage that produces renderings based on a set of supplied RenderedImages at various resolutions.

---

### Field Detail

#### renderedSource

protected transient java.awt.image.RenderedImage[] **renderedSource**  
An array of RenderedImage sources.

---

#### numSources

private int **numSources**

---

#### aspect

protected float **aspect**  
The aspect ratio, derived from the highest-resolution source.

---

#### minX

protected float **minX**  
The min X coordinate in Renderable coordinates.

---

#### minY

protected float **minY**  
The min Y coordinate in Renderable coordinates.

---

#### width

protected float **width**  
The width in Renderable coordinates.

---

#### height

protected float **height**  
The height in Renderable coordinates.

---

### Constructor Detail

#### MultiResolutionRenderableImage

```
public MultiResolutionRenderableImage(java.util.Vector renderedSources,  
                                       float minX,  
                                       float minY,  
                                       float height)
```

Constructs a MultiResolutionRenderableImage with given dimensions from a Vector of progressively lower resolution versions of a RenderedImage.

**Parameters:**

renderedSources - a Vector of RenderedImages.  
 minX - the minimum X coordinate of the Renderable, as a float.  
 minY - the minimum Y coordinate of the Renderable, as a float.  
 height - the height of the Renderable, as a float.

**Throws:**

java.lang.IllegalArgumentException - if the supplied height is non-positive.

## Method Detail

**getSources**

```
public java.util.Vector getSources()
```

Returns an empty Vector, indicating that this RenderableImage has no Renderable sources.

**Specified by:**

getSources in interface java.awt.image.renderable.RenderableImage

**Returns:**

an empty Vector.

**getProperty**

```
public java.lang.Object getProperty(java.lang.String name)
```

Gets a property from the property set of this image. If the property name is not recognized, java.awt.Image.UndefinedProperty will be returned. The default implementation returns java.awt.Image.UndefinedProperty.

**Specified by:**

getProperty in interface java.awt.image.renderable.RenderableImage

**Parameters:**

name - the name of the property to get, as a String.

**Returns:**

a reference to the property Object, or the value java.awt.Image.UndefinedProperty.

**getPropertyNames**

```
public java.lang.String[] getPropertyNames()
```

Returns a list of the properties recognized by this image. If no properties are recognized by this image, null will be returned. The default implementation returns null, i.e., no property names are recognized.

**Specified by:**

getPropertyNames in interface java.awt.image.renderable.RenderableImage

**Returns:**

an array of Strings representing valid property names.

**getWidth**

```
public float getWidth()
```

Returns the floating-point width of the RenderableImage.

**Specified by:**

getWidth in interface java.awt.image.renderable.RenderableImage

**getHeight**

```
public float getHeight()
```

Returns the floating-point height of the RenderableImage.

**Specified by:**

getHeight in interface java.awt.image.renderable.RenderableImage

**getMinX**

```
public float getMinX()
```

Returns the floating-point min X coordinate of the RenderableImage.

**Specified by:**

getMinX in interface java.awt.image.renderable.RenderableImage

---

## getMaxX

public float **getMaxX**()

Returns the floating-point max X coordinate of the RenderableImage.

---

## getMinY

public float **getMinY**()

Returns the floating-point min Y coordinate of the RenderableImage.

**Specified by:**

getMinY in interface java.awt.image.renderable.RenderableImage

---

## getMaxY

public float **getMaxY**()

Returns the floating-point max Y coordinate of the RenderableImage.

---

## isDynamic

public boolean **isDynamic**()

Returns false since successive renderings (that is, calls to createRendering() or createScaledRendering()) with the same arguments will never produce different results.

**Specified by:**

isDynamic in interface java.awt.image.renderable.RenderableImage

---

## createScaledRendering

public java.awt.image.RenderedImage **createScaledRendering**(int width,  
int height,  
java.awt.RenderingHints hints)

Returns a rendering with a given width, height, and rendering hints.

If a JAI rendering hint named JAI.KEY\_INTERPOLATION is provided, its corresponding Interpolation object is used as an argument to the JAI operator used to scale the image. If no such hint is present, an instance of InterpolationNearest is used.

**Specified by:**

createScaledRendering in interface java.awt.image.renderable.RenderableImage

**Parameters:**

width - the width of the rendering in pixels.  
height - the height of the rendering in pixels.  
hints - a Hashtable of rendering hints.

**Throws:**

java.lang.IllegalArgumentException - if width or height are non-positive.

---

## createDefaultRendering

public java.awt.image.RenderedImage **createDefaultRendering**()

Returns the full resolution source RenderedImage with no rendering hints.

**Specified by:**

createDefaultRendering in interface java.awt.image.renderable.RenderableImage

---

## createRendering

public java.awt.image.RenderedImage **createRendering**(java.awt.image.renderable.RenderContext renderContext)

Returns a rendering based on a RenderContext.

If a JAI rendering hint named JAI.KEY\_INTERPOLATION is provided, its corresponding Interpolation object is used as an argument to the JAI operator used to transform the image. If no such hint is present, an instance of InterpolationNearest is used.

The RenderContext may contain a Shape that represents the area-of-interest (aoi). If the aoi is specified, it is still legal to return an image that's larger than this aoi. Therefore, by default, the aoi, if specified, is ignored at the rendering.

**Specified by:**

createRendering in interface java.awt.image.renderable.RenderableImage

**Parameters:**

renderContext - a RenderContext describing the transform rendering hints.

**Throws:**

NullPointerException - if renderContext is null.

---

**writeObject**

```
private void writeObject(java.io.ObjectOutputStream out)
    throws java.io.IOException
```

Serialize the MultiResolutionRenderableImage.

**Parameters:**

out - The stream provided by the VM to which to write the object.

---

**readObject**

```
private void readObject(java.io.ObjectInputStream in)
    throws java.io.IOException,
           java.lang.ClassNotFoundException
```

Deserialize the MultiResolutionRenderableImage.

**Parameters:**

in - The stream provided by the VM from which to read the object.

---

**javax.media.jai**

## **Class NoParameterDefault**

java.lang.Object

└── javax.media.jai.NoParameterDefault

---

class **NoParameterDefault**

extends java.lang.Object

A class that signifies that a parameter has no default value.

---

### **Constructor Detail**

#### **NoParameterDefault**

**NoParameterDefault**( )

---

## javax.media.jai Class NullOpImage

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|   |
|   +-- javax.media.jai.OpImage
|       |
|       +-- javax.media.jai.PointOpImage
|           |
|           +-- javax.media.jai.NullOpImage
```

---

public class **NullOpImage**  
extends PointOpImage

A trivial OpImage subclass that simply transmits its source unchanged. This may be useful when an interface requires an OpImage but another sort of RenderedImage (such as a BufferedImage or TiledImage) is to be used. Additionally, NullOpImage is able to make use of JAI's tile caching mechanisms.

Methods that get or set properties are implemented to forward the requests to the source image; no independent property information is stored in the NullOpImage itself.

---

### Field Detail

#### computeType

protected int **computeType**

### Constructor Detail

#### NullOpImage

```
public NullOpImage(java.awt.image.RenderedImage source,  
                   TileCache cache,  
                   int computeType,  
                   ImageLayout layout)
```

Constructs a NullOpImage. The image bounds are copied from the source image. The tile grid layout, SampleModel, and ColorModel may be overridden by an ImageLayout parameter. The image bounds (min X and Y, width, and height) are always taken from the source image.

The superclass constructor will be passed a new ImageLayout object with all of its fields filled in.

**Parameters:**

source - A RenderedImage.

cache - a TileCache object to store tiles from this OpImage, or null. If null, a default cache will be used.

computeType - A tag indicating whether the source is OpImage.OP\_COMPUTE\_BOUND, OpImage.OP\_IO\_BOUND or OpImage.OP\_NETWORK\_BOUND. This information is used as a hint to optimize OpImage computation.

layout - An ImageLayout describing the layout parameters that will override the corresponding parameters of the source image layout. The image bounds parameters are ignored.

**Throws:**

java.lang.IllegalArgumentException - if combining the source bounds with the layout parameter results in negative output width or height.

### Method Detail

#### layoutHelper

```
private static ImageLayout layoutHelper(java.awt.image.RenderedImage source,  
                                         ImageLayout il)
```

---

## computeTile

```
public java.awt.image.Raster computeTile(int tileX,  
                                           int tileY)
```

Returns a tile for reading.

**Parameters:**

tileX - The X index of the tile.

tileY - The Y index of the tile.

**Returns:**

The tile as a Raster.

**Overrides:**

computeTile in class PointOpImage

---

## computesUniqueTiles

```
public boolean computesUniqueTiles()
```

Returns false as NullOpImage can return via computeTile() tile that are internally cached.

**Overrides:**

computesUniqueTiles in class OpImage

---

## getProperties

```
protected java.util.Hashtable getProperties()
```

Returns the properties from the source image.

**Overrides:**

getProperties in class PlanarImage

---

## setProperties

```
protected void setProperties(java.util.Hashtable properties)
```

Set the properties Hashtable of the source image to the supplied Hashtable.

**Overrides:**

setProperties in class PlanarImage

---

## getPropertyNames

```
public java.lang.String[] getPropertyNames()
```

Returns the property names from the source image or null if no property names are recognized.

**Overrides:**

getPropertyNames in class PlanarImage

---

## getPropertyNames

```
public java.lang.String[] getPropertyNames(java.lang.String prefix)
```

Returns the property names with the supplied prefix from the source image or null if no property names are recognized.

**Overrides:**

getPropertyNames in class PlanarImage

---

## getProperty

```
public java.lang.Object getProperty(java.lang.String name)
```

Retrieves a property from the source image by name or java.awt.Image.UndefinedProperty if the property with the specified name is not defined.

**Overrides:**

getProperty in class PlanarImage

---

## setProperty

```
public void setProperty(java.lang.String name,  
                        java.lang.Object value)
```

Sets a property on the source image by name.

**Overrides:**

setProperty in class PlanarImage

---

## **getOperationComputeType**

public int **getOperationComputeType**()

Returns one of OP\_COMPUTE\_BOUND, OP\_IO\_BOUND, or OP\_NETWORK\_BOUND to indicate how the operation is likely to spend its time. The answer does not affect the output of the operation, but may allow a scheduler to parallelize the computation of multiple operations more effectively. The default implementation returns OP\_COMPUTE\_BOUND.

**Overrides:**

getOperationComputeType in class OpImage

---

## javax.media.jai Class OpImage

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|
+-- javax.media.jai.OpImage
```

### Direct Known Subclasses:

AreaOpImage, PointOpImage, SourcelessOpImage, StatisticsOpImage, UntiledOpImage, WarpOpImage

---

public abstract class **OpImage**  
extends PlanarImage

The parent class for all imaging operations. OpImage centralizes a number of common functions, including connecting sources and sinks during construction of OpImage chains, and tile cache management.

Most significantly, OpImage defines `getTile()` to make calls to the `computeRect()` routine of the subclass, performing cobbling if necessary. Two variants of the `computeRect` method exist. The first is used when the OpImage constructor is called with its `cobbleSources` parameter set to true; it receives cobbled source data in the form of an array of Rasters, one per source.

The second `computeRect` variant is called if `cobbleSources` has been set to false; it receives an array of PlanarImages and is responsible for performing its own source accesses. This variant may be useful if iterators are to be used for the underlying implementation.

Every OpImage subclass must supply overridden versions of at least one of these methods, and specify which one is to be called via the `cobbleSources` constructor argument. If the designated variant has not been overridden, the default implementation will throw a `RuntimeException`.

Many of these functions are overridden in OpImage's direct subclasses, such as PointOpImage and AreaOpImage. These subclasses also implement the abstract methods `mapSourceRect()` and `mapDestRest()`, which describe the relationship between areas in the source and destination images.

---

<b>Field Detail</b>
---------------------

## OP\_COMPUTE\_BOUND

public static final int **OP\_COMPUTE\_BOUND**

A constant indicating that an operation is likely to spend its time mainly performing computation.

---

## OP\_IO\_BOUND

public static final int **OP\_IO\_BOUND**

A constant indicating that an operation is likely to spend its time mainly performing local I/O.

---

## OP\_NETWORK\_BOUND

public static final int **OP\_NETWORK\_BOUND**

A constant indicating that an operation is likely to spend its time mainly performing network I/O.

---

## extenders

protected BorderExtender[] **extenders**

An array of BorderExtenders, one per source, or null. If `extenders` is non-null, there must be a non-null entry for each source.

---

## cobbleSources

protected boolean **cobbleSources**

Set to true if computeRect needs contiguous sources.

---

## formatTags

private RasterFormatTag[] **formatTags**

The default RasterAccessor format tags.

---

## cache

protected transient TileCache **cache**

A reference to a centralized TileCache object.

## Constructor Detail

### OpImage

```
public OpImage(java.util.Vector sources,
               BorderExtender[] extenders,
               TileCache cache,
               ImageLayout layout,
               boolean cobbleSources)
```

Constructs an OpImage, given a Vector of sources.

This constructor makes a copy of the source Vector, wrapping non-JAI sources (using `PlanarImage.wrapRenderedImage()`). Each source is informed that this image is now one of its sinks.

The structure of the output image is determined using the following algorithm.

First, if no source images are present, the min X, min Y, width, height, and SampleModel fields are set using the layout parameter. If layout is null, or one or more of those fields are not set, an `IllegalArgumentException` will be thrown. The tile grid layout fields are copied from the layout, if present. If not, the tile width and height are set to default values and the tile grid is set to start at the image min X and Y.

If one or more source images are present, the layout parameter is combined with the layout of the first source using `PlanarImage.setImageParameters()` to provide initial values for the layout fields other than the image bounds. The bounding rectangles of all sources are intersected, and any of minX, minY, width, and height that were not supplied in the layout parameter are set according to the intersected bounds.

For example, if the intersection of the source bounding rectangles extends from (50, 60) and has width=100 and height=200, the minX field of layout is set to 80, and the height field is set to 90, the output image will begin at (75, 60) and have width=70 (since `getMaxX()` on the intersected rectangle is  $50 + 100 = 150$  and the layout min X is 80), and height=90 (taken directly from the layout).

If the resulting output width or height is negative, an `IllegalArgumentException` will be thrown.

If no SampleModel was explicitly supplied using the layout parameter, one is automatically constructed. The output SampleModel will be interleaved, will have a data type with sufficient range to include all values in the range of any of the sources, and will have a number of bands that is the minimum of that of any of the sources. For the purposes of this computation, a source with an `IndexColorModel` is considered to have as many bands as the number of components in the ColorModel, so a single-banded source with a `ColorModel` outputting RGB components will be treated as having three bands.

It is possible to supply a null SampleModel explicitly using the layout parameter. In this case, the calling constructor must set the sampleModel instance variable manually.

(The `RasterAccessor` class will automatically detect the case of an indexed source and component destination, and perform expansion of the source pixels. If a means other than `RasterAccessor` is used for pixel access, for example iterators, source pixel expansion is the responsibility of the operation implementor.)

Note that the choice of the output data type is based only on the ranges of the source image data types. For example, mixed `TYPE_BYTE` and `TYPE_SHORT` sources will result in `TYPE_SHORT` output. Sources with `TYPE_SHORT` and `TYPE_USHORT` data types will result in an output of type `TYPE_INT`. However, the nature of the operation is not considered so an operation that performs data type conversion must supply its own SampleModel.

If a SampleModel was explicitly supplied, and its width and height match the tile width and height of the image, it is used as-is. If not, and the SampleModel is non-null, `createCompatibleSampleModel()` is called to produce the output SampleModel.

If no ColorModel was explicitly supplied using the layout parameter, one is automatically constructed by calling `PlanarImage.createColorModel()` using the SampleModel derived from the previous step. Note that this may result in a null ColorModel if the SampleModel is null or there is no standard ColorModel available for the SampleModel.

This standard process may be altered in two ways. First, and preferably, the `layout` parameter will contain those values needed to produce the proper output. Second, the subclass constructor may alter the values of any fields it needs to after calling its superclass constructor. However, once the subclass constructor exits, these fields should not be altered further in order to guarantee a consistent state for the `OpImage`.

If the subclass calls `getFormatTags()` in order to obtain a value for use with the `RasterAccessor` class, it should ensure that the `sampleModel` and `colorModel` fields have their final values prior to making the call, since this method caches its result.

**Parameters:**

- `sources` - a `Vector` of sources, or null.
- `extenders` - an array of `BorderExtender` objects, one per source.
- `cache` - a `TileCache` object to store tiles from this `OpImage`, or null. If null, a default cache will be used.
- `layout` - an `ImageLayout`, or null.
- `cobbleSources` - a boolean indicating whether `computeRect` expects contiguous sources.

**Throws:**

- `java.lang.IllegalArgumentException` - if no source is supplied and `layout` is null or does not contain valid values for min X, min Y, width, height, and `SampleModel`.
- `java.lang.IllegalArgumentException` - if combining the intersected source bounds with the `layout` parameter results in negative output width or height.

---

## OpImage

```
public OpImage(java.awt.image.RenderedImage source,
               BorderExtender extender,
               TileCache cache,
               ImageLayout layout,
               boolean cobbleSources)
```

Constructs an `OpImage`, given a single source image.

**Parameters:**

- `source` - a `RenderedImage` source.
- `extender` - a `BorderExtender`, or null.
- `cache` - a `TileCache` object to store tiles from this `OpImage`, or null. If null, a default cache will be used.
- `layout` - an `ImageLayout`, or null.
- `cobbleSources` - a boolean indicating whether `computeRect` expects contiguous sources.

---

## OpImage

```
public OpImage(java.awt.image.RenderedImage source0,
               java.awt.image.RenderedImage source1,
               BorderExtender extender0,
               BorderExtender extender1,
               TileCache cache,
               ImageLayout layout,
               boolean cobbleSources)
```

Constructs an `OpImage`, given two source images.

**Parameters:**

- `source0` - a `RenderedImage` source.
- `source1` - a `RenderedImage` source.
- `extender0` - a `BorderExtender` for source 0, or null.
- `extender1` - a `BorderExtender` for source 1, or null.
- `cache` - a `TileCache` object to store tiles from this `OpImage`, or null. If null, a default cache will be used.
- `layout` - an `ImageLayout`, or null.
- `cobbleSources` - a boolean indicating whether `computeRect` expects contiguous sources.

## Method Detail

### vectorize

```
static java.util.Vector vectorize(java.awt.image.RenderedImage source)
```

A utility method used by constructors to store sources in a `Vector`.

**Parameters:**

- `source` - The source image.

**Returns:**

A Vector containing the source.

---

**vectorize**

```
static java.util.Vector vectorize(java.awt.image.RenderedImage source1,  
                                   java.awt.image.RenderedImage source2)
```

A utility method used by constructors to store sources in a Vector.

**Parameters:**

source1 - The first source image.  
source2 - The second source image.

**Returns:**

A Vector containing the source.

---

**vectorize**

```
static java.util.Vector vectorize(java.awt.image.RenderedImage source1,  
                                   java.awt.image.RenderedImage source2,  
                                   java.awt.image.RenderedImage source3)
```

A utility method used by constructors to store sources in a Vector.

**Parameters:**

source1 - The first source image.  
source2 - The second source image.  
source3 - The third source image.

**Returns:**

A Vector containing the source.

---

**mergeTypes**

```
private static int mergeTypes(int type0,  
                              int type1)
```

Returns a type (one of the enumerated constants from DataBuffer) that has sufficient range to contain values from either of two given types. This corresponds to an upwards move in the type lattice.

Note that the merge of SHORT and USHORT is INT, so it is not correct to simply use the larger of the types.

---

**initializeNoSource**

```
private void initializeNoSource(ImageLayout layout)
```

---

**initialize**

```
private void initialize(BorderExtender[] extenders,  
                        ImageLayout layout,  
                        boolean cobbleSources)
```

---

**setTileCache**

```
public void setTileCache(TileCache cache)
```

Sets the tile cache of this image. If null, no caching will be performed. Any previously set cache will be informed that it may release this image's tiles.

**Parameters:**

cache - a TileCache object, or null if no caching is desired.

---

**getTileFromCache**

```
protected java.awt.image.Raster getTileFromCache(int tileX,  
                                                  int tileY)
```

Gets a tile from the cache by location.

**Parameters:**

tileX - the X index of the tile.  
tileY - the Y index of the tile.

**Returns:**  
the tile as a Raster.

---

## addTileToCache

```
protected void addTileToCache(int tileX,  
                             int tileY,  
                             java.awt.image.Raster tile)
```

Adds a tile at a given location to the cache.

**Parameters:**  
tileX - the X index of the tile.  
tileY - the Y index of the tile.  
tile - the tile as a Raster.

---

## getTile

```
public java.awt.image.Raster getTile(int tileX,  
                                     int tileY)
```

Gets a tile for reading.

**Parameters:**  
tileX - the X index of the tile.  
tileY - the Y index of the tile.

**Overrides:**  
getTile in class PlanarImage

---

## computesUniqueTiles

```
public boolean computesUniqueTiles()
```

Returns true if the OpImage returns a unique Raster object every time computeTile() is called. OpImages that internally cache Rasters and return them via computeTile() should return false for this method.

---

## computeTile

```
public java.awt.image.Raster computeTile(int tileX,  
                                           int tileY)
```

The internal counterpart of getTile(). The getTile() method may perform optimizations such as compute scheduling and interaction with a TileCache. This method, on the other hand, is responsible only for computing a particular tile, without regard to its eventual disposition.

The default implementation of the method simply cobbles all of the necessary source data, if cobbleSources was set to be true at construction time, and calls the appropriate variant of computeRect.

More efficient, specialized implementations are provided by subclasses such as AreaOpImage, PointOpImage, SourcelessOpImage, and WarpOpImage.

Note that this method should generally only be called by an implementation of TileScheduler. Normal users should generally call getTile which automatically takes advantage of caching and scheduling to reuse results and increase performance.

---

## finalize

```
protected void finalize()  
    throws java.lang.Throwable
```

Uncache all tiles when this image is garbage collected.

**Overrides:**  
finalize in class PlanarImage

---

## computeRect

```
protected void computeRect(java.awt.image.Raster[] sources,  
                           java.awt.image.WritableRaster dest,  
                           java.awt.Rectangle destRect)
```

Computes a rectangle of output, given Raster sources. This method should be overridden by OpImage subclasses that make use of cobbled sources, as determined by the setting of the cobbleSources constructor argument to this class.

The source Rasters are guaranteed to include at least the area specified by `mapDestRect(destRect)`. Only the specified destination region should be written.

Since the subclasses of `OpImage` may choose between the cobbling and non-cobbling versions of `computeRect`, it is not possible to leave this method abstract in `OpImage`. Instead, a default implementation is provided that throws a `RuntimeException`.

**Parameters:**

`sources` - an array of source Rasters, one per source image.  
`dest` - a `WritableRaster` to be filled in.  
`destRect` - the `Rectangle` within the destination to be written.

**Throws:**

`java.lang.RuntimeException` - if a subclass sets `cobbleSources` to `true` but does not supply an implementation of this method.

---

## computeRect

```
protected void computeRect(PlanarImage[] sources,  
                           java.awt.image.WritableRaster dest,  
                           java.awt.Rectangle destRect)
```

Computes a rectangle of output, given `PlanarImage` sources. This method should be overridden by `OpImage` subclasses that do not require cobbled sources; typically they will instantiate iterators to perform source access, but they may access sources directly (via the `SampleModel/DataBuffer` interfaces) if they wish.

Since the subclasses of `OpImage` may choose between the cobbling and non-cobbling versions of `computeRect`, it is not possible to leave this method abstract in `OpImage`. Instead, a default implementation is provided that throws a `RuntimeException`.

**Parameters:**

`sources` - an array of `PlanarImage` sources.  
`dest` - a `WritableRaster` to be filled in.  
`destRect` - the `Rectangle` within the destination to be written.

**Throws:**

`java.lang.RuntimeException` - if a subclass sets `cobbleSources` to `false` but does not supply an implementation of this method.

---

## getOperationComputeType

```
public int getOperationComputeType()
```

Returns one of `OP_COMPUTE_BOUND`, `OP_IO_BOUND`, or `OP_NETWORK_BOUND` to indicate how the operation is likely to spend its time. The answer does not affect the output of the operation, but may allow a scheduler to parallelize the computation of multiple operations more effectively. The default implementation returns `OP_COMPUTE_BOUND`.

---

## mapSourceRect

```
public abstract java.awt.Rectangle mapSourceRect(java.awt.Rectangle sourceRect,  
                                                  int sourceIndex)
```

Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**Parameters:**

`sourceRect` - the `Rectangle` in source coordinates.  
`sourceIndex` - the index of the source image.

**Returns:**

a `Rectangle` indicating the potentially affected destination region, or `null` if the region is unknown.

**Throws:**

`java.lang.IllegalArgumentException` - if the source index is negative or greater than that of the last source.  
`NullPointerException` - if `sourceRect` is `null`.

---

## mapDestRect

```
public abstract java.awt.Rectangle mapDestRect(java.awt.Rectangle destRect,  
                                                int sourceIndex)
```

Returns a conservative estimate of the region of a specified source that is required in order to compute the pixels of a given destination rectangle.

**Parameters:**

`destRect` - the `Rectangle` in destination coordinates.  
`sourceIndex` - the index of the source image.

**Returns:**

a `Rectangle` indicating the required source region.

**Throws:**

`java.lang.IllegalArgumentException` - if the source index is negative or greater than that of the last source.  
`NullPointerException` - if `destRect` is null.

## getTileDependencies

```
public java.awt.Point[] getTileDependencies(int tileX,
                                             int tileY,
                                             int sourceIndex)
```

Returns a list of indices of the tiles of a given source image that may be required in order to compute a given tile. Ideally, only tiles that will be requested by means of calls to the source's `getTile()` method should be reported. The default implementation uses `mapDestRect()` to obtain a conservative estimate.

If no dependencies exist because the image has no sources, null is returned.

This method may be used by optimized implementations of JAI in order to predict future work and create an optimized schedule for performing it.

A given `OpImage` may mix calls to `getTile()` with calls to other methods such as `getData()` and `copyData()` in order to avoid requesting entire tiles where only a small portion is needed. In such a case, this method may be overridden to provide a more accurate estimate of the set of `getTile()` calls that will actually be performed.

**Parameters:**

`tileX` - the X index of the tile.  
`tileY` - the Y index of the tile.  
`sourceIndex` - the index of the source image.

**Returns:**

an array of `Points` indicating the source tile dependencies.

## getTiles

```
public java.awt.image.Raster[] getTiles(java.awt.Point[] tileIndices)
```

Computes the tiles indicated by the given tile indices. This call is preferable to a series of `getTile()` calls because certain implementations can make optimizations based on the knowledge that multiple tiles are being asked for at once.

**Parameters:**

`tileIndices` - An array of `Points` representing tile indices.

**Returns:**

An array of `Rasters` containing the tiles corresponding to the given tile indices.

**Overrides:**

`getTiles` in class `PlanarImage`

## prefetchTiles

```
public void prefetchTiles(java.awt.Point[] tileIndices)
```

Hints that the given tiles might be needed in the near future. Some implementations may spawn one or more threads to compute the tiles, while others may ignore the hint.

**Parameters:**

`tileIndices` - A list of tile indices indicating which tiles to prefetch.

**Overrides:**

`prefetchTiles` in class `PlanarImage`

## hasExtender

```
public boolean hasExtender(int sourceIndex)
```

Indicates whether the source with the given index has a `BorderExtender`. If the source index is out of bounds for the source vector of this `OpImage` then an `ArrayIndexOutOfBoundsException` may be thrown.

**Parameters:**

`sourceIndex` - The index of the source in question.

**Returns:**

true if the indicated source has an extender.

### **getExpandedNumBands**

```
public static int getExpandedNumBands(java.awt.image.SampleModel sampleModel,  
                                       java.awt.image.ColorModel colorModel)
```

Returns the effective number of bands of an image with a given `SampleModel` and `ColorModel`. Normally, this is given by `sampleModel.getNumBands()`, but for images with an `IndexColorModel` the effective number of bands is given by `colorModel.getNumComponents()`, since a single physical sample represents multiple color components.

---

### **getAppropriateDataType**

```
private static int getAppropriateDataType(java.awt.image.SampleModel sampleModel)
```

---

### **getFormatTags**

```
protected RasterFormatTag[] getFormatTags()
```

Returns the image's format tags to be used with a `RasterAccessor`.

This method will compute and cache the tags the first time it is called on a particular image. The image's `SampleModel` and `ColorModel` must be set to their final values before calling this method.

---

## javax.media.jai Interface OperationDescriptor

All Known Implementing Classes:  
OperationDescriptorImpl

---

public abstract interface **OperationDescriptor**

This interface provides a comprehensive description of a specific image operation. All information regarding the operation, such as its name, version, input, and property, should be listed. Any conditions placed on the operation, such as its input format and legal parameter range, should also be included, and the methods to enforce these conditions should be implemented. A set of `PropertyGenerators` may be specified to be used as a basis for the operation's property management.

Each family of the image operation in JAI must have a descriptor that implements this interface. The following basic resource data must be provided:

- A global operation name that is visible to all and is the same in all `Locales`.
- A localized operation name that may be used as a synonym for the global operation name.
- The name of the vendor defining this operation.
- A brief description of this operation.
- An URL where additional documentation on this operation may be found.
- The version of this operation.

Additional information must be provided when appropriate. Only then can this operation be added to an `OperationRegistry`. Furthermore, it is recommended that a detailed description of the operation's functionality be documented in the class comment.

There are two image modes in JAI: the "rendered" mode and the "renderable" mode. An operation supporting the rendered mode takes `RenderedImage`s as its sources, can only be used in a rendered operation chain, and produces a `RenderedImage`. An operation supporting the renderable mode takes `RenderableImage`s as its sources, can only be used in a renderable operation chain, and produces a `RenderableImage`. Therefore, the class types of the sources and the destination of an operation are different between the two modes, but the parameters must be the same for both modes.

Those operations that support the rendered mode must specify this feature using the `isRenderedSupported()` method and implement those methods that supply the additional information for the rendered mode. Those operations that support the renderable mode must specify this feature using the `isRenderableSupported()` method and implement those methods that supply the additional information for the renderable mode.

JAI

---

### Field Detail

#### **NO\_PARAMETER\_DEFAULT**

public static final java.lang.Object **NO\_PARAMETER\_DEFAULT**

An Object that signifies that a parameter has no default value.

### Method Detail

#### **getResources**

public java.lang.String[][] **getResources**(java.util.Locale locale)

Returns the resource data for this operation in the specified `Locale`. It must contain `String` data for the following tags:

- "GlobalName" - A global operation name that is visible to all and is the same in all `Locales`.
- "LocalName" - A localized operation name that may be used as a synonym for the "GlobalName".
- "Vendor" - The name of the vendor defining this operation.
- "Description" - A brief description of this operation.
- "DocURL" - An URL where additional documentation on this operation may be found.
- "Version" - A free-form version indicator of this operation.

In addition, it may contain `String` data for the following tags when appropriate:

- "arg0Desc", "arg1Desc", ... - Description of the input parameters.
- "hint0Desc", "hint1Desc", ... - Description of the rendering hints.

**Parameters:**

locale - The `Locale` for which the information should be localized. It may be different from the default `Locale`.

**Returns:**

A two-dimensional array of `Strings` containing the mandatory and optional resource tags and their corresponding resource data.

---

**getResourceBundle**

```
public java.util.ResourceBundle getResourceBundle(java.util.Locale locale)
```

Returns the resource data for this operation in the specified `Locale` in a `ResourceBundle`. The resource data values are taken from the `getResources()` method which must be implemented by each operation descriptor.

**Parameters:**

`locale` - The `Locale` for which the information should be localized. It may be different from the default `Locale`.

**Returns:**

A `ResourceBundle` containing the mandatory and optional resource information.

---

**getPropertyGenerators**

```
public PropertyGenerator[] getPropertyGenerators()
```

Returns an array of `PropertyGenerators` implementing the property inheritance for this operation. They may be used as a basis for the operation's property management.

**Returns:**

An array of `PropertyGenerators`, or `null` if this operation does not have any of its own `PropertyGenerators`.

---

**getName**

```
public java.lang.String getName()
```

Returns the name of this operation; this is the same as the `GlobalName` value in the resources.

**Returns:**

A `String` representing the operation's global name.

---

**getNumSources**

```
public int getNumSources()
```

Returns the number of sources required by this operation.

---

**isRenderedSupported**

```
public boolean isRenderedSupported()
```

Returns `true` if this operation supports the rendered image mode. That is, it may be performed on `RenderedImage` sources in a rendered operation chain, and produces a rendered result. The `JAI.create()` method should be used to instantiate the operation.

---

**isImmediate**

```
public boolean isImmediate()
```

Returns `true` if the operation should be rendered immediately during the call to `JAI.create()`; that is, the operation is placed in immediate mode. If `true`, and the rendering fails, `null` will be returned from `JAI.create()`. If `false`, `JAI.create()` will return an instance of the `RenderedOp` that may be asked to render itself at a later time; this rendering may fail silently at that time. This method applies to the rendered mode only.

Operations that rely on an external resource, such as a source file, or that produce externally-visible side effects, such as writing to an output file, should return `true` from this method. Operations that rely only on their sources and parameters usually wish to return `false` in order to defer rendering as long as possible.

---

**getSourceClasses**

```
public java.lang.Class[] getSourceClasses()
```

Returns an array of `Classes` that describe the types of sources required by this operation in the rendered image mode. If this operation has no source, this method returns `null`.

---

## getDestClass

```
public java.lang.Class getDestClass()
```

Returns a `Class` that describes the type of destination this operation produces in the rendered image mode. Currently JAI supports two destination class types: `java.awt.image.RenderedImage.class` and `java.util.Collection.class`.

---

## validateArguments

```
public boolean validateArguments(java.awt.image.renderable.ParameterBlock args,  
                                 java.lang.StringBuffer msg)
```

Returns `true` if this operation is capable of handling the input rendered source(s) and/or parameter(s) specified in the `ParameterBlock`, or `false` otherwise, in which case an explanatory message may be appended to the `StringBuffer`.

This method is the standard place where input arguments are validated against this operation's specification for the rendered mode. It is called by `JAI.create()` as a part of its validation process. Thus it is strongly recommended that the application programs use the `JAI.create()` methods to instantiate all the rendered operations.

This method sets all the undefined parameters in the `ParameterBlock` to their default values, if the default values are specified.

### Parameters:

`args` - Input arguments, including source(s) and/or parameter(s).  
`msg` - A string that may contain error messages.

---

## isRenderableSupported

```
public boolean isRenderableSupported()
```

Returns `true` if this operation supports the renderable image mode. That is, it may be performed on `RenderableImage` sources in a renderable operation chain, and produces a renderable result. The `JAI.createRenderable()` method should be used to instantiate the operation.

If this method returns `true`, all the additional methods that supply the renderable mode information must be implemented.

---

## getRenderableSourceClasses

```
public java.lang.Class[] getRenderableSourceClasses()
```

Returns an array of `Classes` that describe the types of sources required by this operation in the renderable image mode. If this operation does not support the renderable mode, or if it has no source, this method returns `null`.

---

## getRenderableDestClass

```
public java.lang.Class getRenderableDestClass()
```

Returns a `Class` that describes the type of destination this operation produces in the renderable image mode. Currently JAI supports two destination class types: `java.awt.image.renderable.RenderableImage.class` and `java.util.Collection.class`.

---

## validateRenderableArguments

```
public boolean validateRenderableArguments(java.awt.image.renderable.ParameterBlock args,  
                                           java.lang.StringBuffer msg)
```

Returns `true` if this operation is capable of handling the input renderable source(s) and/or parameter(s) specified in the `ParameterBlock`, or `false` otherwise, in which case an explanatory message may be appended to the `StringBuffer`.

This method is the standard place where input arguments are validated against this operation's specification for the renderable mode. It is called by `JAI.createRenderable()` as a part of its validation process. Thus it is strongly recommended that the application programs use the `JAI.createRenderable()` method to instantiate all the renderable operations.

This method sets all the undefined parameters in the `ParameterBlock` to their default values, if the default values are specified.

If this operation does not support the renderable mode, this method returns `false` regardless of the input arguments

### Parameters:

`args` - Input arguments, including source(s) and/or parameter(s).  
`msg` - A string that may contain error messages.

---

## getNumParameters

```
public int getNumParameters()
```

Returns the number of parameters (not including the sources) required by this operation.

---

## getParamClasses

```
public java.lang.Class[] getParamClasses()
```

Returns an array of `Classes` that describe the types of parameters required by this operation. If this operation has no parameter, this method returns `null`.

---

## getParamNames

```
public java.lang.String[] getParamNames()
```

Returns an array of `Strings` that are the localized parameter names of this operation. If this operation has no parameter, this method returns `null`.

---

## getParamDefaults

```
public java.lang.Object[] getParamDefaults()
```

Returns an array of `Objects` that define the default values of the parameters for this operation. Default values may be `null`. When instantiating the operation, the default values may be used for those parameters whose values are not supplied. The `NO_PARAMETER_DEFAULT` static `Object` indicates that a parameter has no default value. If this operation has no parameter, this method returns `null`.

---

## getParamDefaultValue

```
public java.lang.Object getParamDefaultValue(int index)
```

Returns the default value of a specified parameter. The default value may be `null`. If a parameter has no default value, this method returns `NO_PARAMETER_DEFAULT`.

**Parameters:**

`index` - The index of the parameter whose default value is queried.

**Throws:**

`NullPointerException` - if this operation has no parameter.

`ArrayIndexOutOfBoundsException` - if there is no parameter corresponding to the specified `index`.

---

## getParamMinValue

```
public java.lang.Number getParamMinValue(int index)
```

Returns the minimum legal value of a specified numeric parameter for this operation. If the specified parameter is non-numeric, this method returns `null`.

The return value should be of the class type appropriate for the parameter's type, that is, `Byte` for a byte parameter, `Integer` for an `int` parameter, and so forth.

**Parameters:**

`index` - The index of the numeric parameter whose minimum value is queried.

**Returns:**

A `Number` representing the minimum legal value of the queried parameter, or `null`.

**Throws:**

`NullPointerException` - if this operation has no parameter.

`ArrayIndexOutOfBoundsException` - if there is no parameter corresponding to the specified `index`.

---

## getParamMaxValue

```
public java.lang.Number getParamMaxValue(int index)
```

Returns the maximum legal value of a specified numeric parameter for this operation. If the specified parameter is non-numeric, this method returns `null`.

The return value should be of the class type appropriate for the parameter's type, that is, `Byte` for a byte parameter, `Integer` for an `int` parameter, and so forth.

**Parameters:**

`index` - The index of the numeric parameter whose maximum value is queried.

**Returns:**

A Number representing the maximum legal value of the queried parameter, or null.

**Throws:**

NullPointerException - if this operation has no parameter.

ArrayIndexOutOfBoundsException - if there is no parameter corresponding to the specified index.

---

**javax.media.jai**

## **Class OperationDescriptorImpl**

java.lang.Object

|-- **javax.media.jai.OperationDescriptorImpl**

### **Direct Known Subclasses:**

AbsoluteDescriptor, AddCollectionDescriptor, AddConstDescriptor, AddConstToCollectionDescriptor, AddDescriptor, AffineDescriptor, AndConstDescriptor, AndDescriptor, AWTImageDescriptor, BandCombineDescriptor, BandSelectDescriptor, BMPDescriptor, BorderDescriptor, BoxFilterDescriptor, ClampDescriptor, ColorConvertDescriptor, CompositeDescriptor, ConjugateDescriptor, ConstantDescriptor, ConvolveDescriptor, CropDescriptor, DCTDescriptor, DFTDescriptor, DivideByConstDescriptor, DivideComplexDescriptor, DivideDescriptor, DivideIntoConstDescriptor, EncodeDescriptor, ErrorDiffusionDescriptor, ExpDescriptor, ExtremaDescriptor, FileLoadDescriptor, FileStoreDescriptor, FormatDescriptor, FPXDescriptor, GIFDescriptor, GradientMagnitudeDescriptor, HistogramDescriptor, IDCTDescriptor, IDFTDescriptor, IIPDescriptor, IIPResolutionDescriptor, ImageFunctionDescriptor, InvertDescriptor, JPEGDescriptor, LogDescriptor, LookupDescriptor, MagnitudeDescriptor, MagnitudeSquaredDescriptor, MatchCDFDescriptor, MaxDescriptor, MeanDescriptor, MedianFilterDescriptor, MinDescriptor, MultiplyComplexDescriptor, MultiplyConstDescriptor, MultiplyDescriptor, NotDescriptor, OrConstDescriptor, OrderedDitherDescriptor, OrDescriptor, OverlayDescriptor, PatternDescriptor, PeriodicShiftDescriptor, PhaseDescriptor, PiecewiseDescriptor, PNGDescriptor, PNMDescriptor, PolarToComplexDescriptor, RenderableDescriptor, RescaleDescriptor, RotateDescriptor, ScaleDescriptor, ShearDescriptor, StreamDescriptor, SubtractConstDescriptor, SubtractDescriptor, SubtractFromConstDescriptor, ThresholdDescriptor, TIFFDescriptor, TranslateDescriptor, TransposeDescriptor, URLDescriptor, WarpDescriptor, XorConstDescriptor, XorDescriptor

---

public abstract class **OperationDescriptorImpl**

extends java.lang.Object

implements OperationDescriptor

This class provides a concrete implementation of the OperationDescriptor interface, and is suitable for subclassing.

### **See Also:**

OperationDescriptor

---

## **Field Detail**

### **resources**

protected java.lang.String[][] **resources**

The resource tags and their corresponding data, stored as an two-dimensional String array.

---

### **sourceClasses**

protected java.lang.Class[] **sourceClasses**

An array of Classes that describe the types of sources required by this operation in the rendered mode.

---

### **renderableSourceClasses**

protected java.lang.Class[] **renderableSourceClasses**

An array of Classes that describe the types of sources required by this operation in the renderable mode. The length of this array must be the same as the length of the sourceClasses array.

---

### **paramClasses**

protected java.lang.Class[] **paramClasses**

An array of Classes that describe the types of parameters required by this operation.

---

### **paramNames**

protected java.lang.String[] **paramNames**

An array of Strings that are the localized parameter names of this operation. The names must be listed in the same order corresponding to the parameter Classes.

---

## paramDefaults

protected java.lang.Object[] **paramDefaults**

An array of Objects that define the default values of the parameters of this operation. The values must be listed in the same order corresponding to the parameter Classes. The default value may be null. The `OperationDescriptor.NO_PARAMETER_DEFAULT` static Object indicates that a parameter has no default value.

---

## name

private java.lang.String **name**

The global name of this operation.

## Constructor Detail

### OperationDescriptorImpl

```
public OperationDescriptorImpl(java.lang.String[][] resources,
                               java.lang.Class[] sourceClasses,
                               java.lang.Class[] renderableSourceClasses,
                               java.lang.Class[] paramClasses,
                               java.lang.String[] paramNames,
                               java.lang.Object[] paramDefaults)
```

Constructor.

#### Parameters:

`resources` - The resource tags and their corresponding data.  
`sourceClasses` - The source types required by this operation in the rendered mode. It may be null if this operation does not support the rendered mode, or if it has no sources.  
`renderableSourceClasses` - The source types required by this operation in the renderable mode. It may be null if this operation does not support the renderable mode, or if it has no sources.  
`paramClasses` - The parameter types required by this operation. It may be null if this operation has no parameters.  
`paramNames` - The localized parameter names. It may be null if this operation has no parameters.  
`paramDefaults` - The parameter default values. It may be null if this operation has no parameters, or none of the parameters has a default value.

#### Throws:

`NullPointerException` - if `resources` is null.  
`NullPointerException` - if this operation supports the rendered mode, and it has sources, and `sourceClasses` is null.  
`NullPointerException` - if this operation supports the renderable mode, and it has sources, and `renderableSourceClasses` is null.  
`java.lang.IllegalArgumentException` - if `sourceClasses` and `renderableSourceClasses` (if both are not null) do not have the same number of elements.  
`NullPointerException` - if this operation has parameters and `paramClasses` or `paramNames` is null.  
`java.lang.IllegalArgumentException` - if this operation has parameters and `paramClasses`, `paramNames`, and `paramDefaults` (if all are not null) do not all have the same number of elements.

---

### OperationDescriptorImpl

```
public OperationDescriptorImpl(java.lang.String[][] resources,
                               java.lang.Class[] sourceClasses)
```

Constructor for operations that supports only the rendered mode and requires no parameters.

#### Parameters:

`resources` - The resource tags and their corresponding data.  
`sourceClasses` - The source types required by this operation in the rendered mode. It may be null if this operation has no sources.

#### Throws:

`NullPointerException` - if `resources` is null.

---

### OperationDescriptorImpl

```
public OperationDescriptorImpl(java.lang.String[][] resources,
                               java.lang.Class[] sourceClasses,
                               java.lang.Class[] renderableSourceClasses)
```

Constructor for operations that supports either the rendered or the renderable or both modes and requires no parameters.

**Parameters:**

`resources` - The resource tags and their corresponding data.  
`sourceClasses` - The source types required by this operation in the rendered mode. It may be null if this operation does not support the rendered mode, or if it has no sources.  
`renderableSourceClasses` - The source types required by this operation in the renderable mode. It may be null if this operation does not support the renderable mode, or if it has no sources.

**Throws:**

`NullPointerException` - if `resources` is null.  
`NullPointerException` - if this operation supports the rendered mode, and it has sources, and `sourceClasses` is null.  
`NullPointerException` - if this operation supports the renderable mode, and it has sources, and `renderableSourceClasses` is null.  
`java.lang.IllegalArgumentException` - if `sourceClasses` and `renderableSourceClasses` (if both are not null) do not have the same number of elements.

---

**OperationDescriptorImpl**

```
public OperationDescriptorImpl(java.lang.String[][] resources,
                               java.lang.Class[] paramClasses,
                               java.lang.String[] paramNames,
                               java.lang.Object[] paramDefaults)
```

Constructor for operations that supports either the rendered or the renderable or both modes and requires no sources.

**Throws:**

`NullPointerException` - if `resources` is null.  
`NullPointerException` - if this operation has parameters and `paramClasses` or `paramNames` is null.  
`java.lang.IllegalArgumentException` - if this operation has parameters and `paramClasses`, `paramNames`, and `paramDefaults` (if not null) do not all have the same number of elements.

---

**OperationDescriptorImpl**

```
public OperationDescriptorImpl(java.lang.String[][] resources,
                               int numSources,
                               java.lang.Class[] paramClasses,
                               java.lang.String[] paramNames,
                               java.lang.Object[] paramDefaults)
```

Constructor for operations that supports either the rendered or the renderable or both modes. The class type for all the source(s) of the rendered mode (if supported) is set to `java.awt.image.RenderedImage.class`. The class type for all the source(s) of the renderable mode (if supported) is set to `java.awt.image.renderable.RenderableImage`.

**Parameters:**

`resources` - The resource tags and their corresponding data.  
`numSources` - The number of sources required by this operation. It should not be negative. A negative value indicates this operation has no sources.  
`paramClasses` - The parameter types required by this operation. It may be null if this operation has no parameters.  
`paramNames` - The localized parameter names. It may be null if this operation has no parameters.  
`paramDefaults` - The parameter default values. It may be null if this operation has no parameters, or none of the parameters has a default value.

**Throws:**

`NullPointerException` - if `resources` is null.  
`NullPointerException` - if this operation has parameters and `paramClasses` or `paramNames` is null.  
`java.lang.IllegalArgumentException` - if this operation has parameters and `paramClasses`, `paramNames`, and `paramDefaults` (if not null) do not all have the same number of elements.

---

**OperationDescriptorImpl**

```
public OperationDescriptorImpl(java.lang.String[][] resources,
                               int numSources)
```

Constructor for operations that support the rendered mode and possibly the renderable mode and require no parameters. The class type for all the source(s) of the rendered mode is set to `java.awt.image.RenderedImage.class`. The class type for all the source(s) of the renderable mode (if supported) is set to `java.awt.image.renderable.RenderableImage`.

**Parameters:**

`resources` - The resource tags and their corresponding data.  
`numSources` - The number of sources required by this operation. It should not be negative. A negative value indicates this operation has no sources.

**Throws:**

NullPointerException - if `resources` is null.

## Method Detail

### getResources

```
public java.lang.String[][] getResources(java.util.Locale locale)
```

Returns the resource data for this operation. It must contain `String` data for the following tags: "GlobalName", "LocalName", "Vendor", "Description", "DocURL", and "Version". Additional resources should be supplied when appropriate.

The default implementation simply returns a reference to the local "resources" variable, which should be supplied by each subclass by way of the superclass constructor. It also ignores the `Locale` argument, and always returns the `Strings` in the default `Locale`.

**Specified by:**

`getResources` in interface `OperationDescriptor`

**Parameters:**

`locale` - The `Locale` in which to localize the resource data.

### getResourceBundle

```
public java.util.ResourceBundle getResourceBundle(java.util.Locale locale)
```

Returns the resource data for this operation in a `ResourceBundle`. The resource data are taken from the `getResources()` method.

The default implementation ignores the `Locale` argument, and always returns the resources in the default `Locale`.

**Specified by:**

`getResourceBundle` in interface `OperationDescriptor`

**Parameters:**

`locale` - The `Locale` in which to localize the resource data.

**Returns:**

A `ResourceBundle` containing mandatory and optional resource information.

### getPropertyGenerators

```
public PropertyGenerator[] getPropertyGenerators()
```

Returns an array of `PropertyGenerators` implementing the property inheritance for this operation. The default implementation returns null, indicating that source properties are simply copied. Subclasses should override this method if they wish to produce inherited properties.

**Specified by:**

`getPropertyGenerators` in interface `OperationDescriptor`

### getName

```
public java.lang.String getName()
```

Returns the name of this operation; this is the same as the `GlobalName` value in the resources and is visible to all.

**Specified by:**

`getName` in interface `OperationDescriptor`

**Returns:**

A `String` representing the operation's global name.

**Throws:**

`MissingResourceException` - if the `GlobalName` resource value is not supplied in the resources.

### getNumSources

```
public int getNumSources()
```

Returns the number of sources required by this operation.

**Specified by:**

`getNumSources` in interface `OperationDescriptor`

## isRenderedSupported

public boolean **isRenderedSupported**()

Returns true if this operation supports the rendered mode. The default implementation in this class returns true.

**Specified by:**

isRenderedSupported in interface OperationDescriptor

---

## isImmediate

public boolean **isImmediate**()

Returns true if the operation should be rendered immediately during the call to `JAI.create()`; that is, the operation is placed in immediate mode.

The default implementation in this class returns false so that deferred execution is invoked. Operations that wish to be placed in the immediate mode must override this implementation.

**Specified by:**

isImmediate in interface OperationDescriptor

---

## getSourceClasses

public java.lang.Class[] **getSourceClasses**()

Returns the source class types of this operation for the rendered mode. If this operation has no sources, or if it does not support the rendered mode, this method returns null.

**Specified by:**

getSourceClasses in interface OperationDescriptor

---

## getDestClass

public java.lang.Class **getDestClass**()

Returns the destination class type of this operation for the rendered mode. The default implementation in this class returns `java.awt.image.RenderedImage.class` if this operation supports the rendered mode, or null otherwise.

**Specified by:**

getDestClass in interface OperationDescriptor

---

## validateArguments

public boolean **validateArguments**(java.awt.image.renderable.ParameterBlock args,  
java.lang.StringBuffer msg)

Returns true if this operation supports the rendered mode, and is capable of handling the input arguments for the rendered mode. The default implementation validates both the source(s) and the parameter(s).

Additional validations should be added by each individual operation based on its specification.

**Specified by:**

validateArguments in interface OperationDescriptor

**Throws:**

NullPointerException - if args is null.

NullPointerException - if msg is null and the validation fails.

---

## isRenderableSupported

public boolean **isRenderableSupported**()

Returns true if this operation supports the renderable mode. The default implementation in this class returns false.

Operations that support the renderable mode must override this implementation.

**Specified by:**

isRenderableSupported in interface OperationDescriptor

---

## getRenderableSourceClasses

public java.lang.Class[] **getRenderableSourceClasses**()

Returns the source class types of this operation for the renderable mode. If this operation has no sources, or if it does not support the renderable mode, this method returns null.

**Specified by:**

getRenderableSourceClasses in interface OperationDescriptor

---

## getRenderableDestClass

```
public java.lang.Class getRenderableDestClass()
```

Returns the destination class type of this operation for the renderable mode. The default implementation in this class returns `java.awt.image.renderable.RenderableImage.class` if this operation supports the renderable mode, or `null` otherwise.

**Specified by:**

`getRenderableDestClass` in interface `OperationDescriptor`

---

## validateRenderableArguments

```
public boolean validateRenderableArguments(java.awt.image.renderable.ParameterBlock args,  
                                           java.lang.StringBuffer msg)
```

Returns `true` if this operation supports the renderable mode, and is capable of handling the input arguments for the renderable mode. The default implementation validates both the source(s) and the parameter(s).

If this operation does not support the renderable mode, this method returns `false` regardless of the input arguments.

Additional validations should be added by each individual operation based on its specification.

**Specified by:**

`validateRenderableArguments` in interface `OperationDescriptor`

**Throws:**

`NullPointerException` - if `args` is `null`.

`NullPointerException` - if `msg` is `null` and the validation fails.

---

## getNumParameters

```
public int getNumParameters()
```

Returns the number of parameters (not including sources) required by this operation.

**Specified by:**

`getNumParameters` in interface `OperationDescriptor`

---

## getParamClasses

```
public java.lang.Class[] getParamClasses()
```

Returns the parameter class types of this operation. If this operation has no parameters, this method returns `null`.

**Specified by:**

`getParamClasses` in interface `OperationDescriptor`

---

## getParamNames

```
public java.lang.String[] getParamNames()
```

Returns the localized parameter names of this operation. If this operation has no parameters, this method returns `null`.

**Specified by:**

`getParamNames` in interface `OperationDescriptor`

---

## getParamDefaults

```
public java.lang.Object[] getParamDefaults()
```

Returns the default values of the parameters for this operation. If this operation has no parameters, this method returns `null`. If a parameter does not have a default value, the constant `OperationDescriptor.NO_PARAMETER_DEFAULT` should be used. The `validateArguments()` and `validateRenderableArguments` method will return `false` if an input parameter without a default value is supplied as `null`, or if an unspecified trailing parameter does not have a default value.

**Specified by:**

`getParamDefaults` in interface `OperationDescriptor`

---

## getParamDefaultValue

```
public java.lang.Object getParamDefaultValue(int index)
```

Returns the default value of specified parameter. The default value may be `null`. If a parameter has no default value, this method returns `OperationDescriptor.NO_PARAMETER_DEFAULT`.

**Specified by:**

getParamDefaultValue in interface OperationDescriptor

**Parameters:**

index - The index of the parameter whose default value is queried.

**Throws:**

NullPointerException - if this operation has no parameters.

ArrayIndexOutOfBoundsException - if there is no parameter corresponding to the specified index.

---

## getParamMinValue

```
public java.lang.Number getParamMinValue(int index)
```

Returns the minimum legal value of a specified numeric parameter for this operation. If the specified parameter is non-numeric, this method returns null.

The return value should be of the class type appropriate for the parameter's type, that is, Byte for a byte parameter, Integer for an int parameter, and so forth.

The default implementation returns the minimum value in the parameter data type's full range.

**Specified by:**

getParamMinValue in interface OperationDescriptor

**Parameters:**

index - The index of the parameter to be queried.

**Returns:**

A Number representing the minimum legal value, or null if the specified parameter is not numeric.

**Throws:**

NullPointerException - if this operation has no parameters.

ArrayIndexOutOfBoundsException - if there is no parameter corresponding to the specified index.

---

## getParamMaxValue

```
public java.lang.Number getParamMaxValue(int index)
```

Returns the maximum legal value of a specified numeric parameter for this operation. If the specified parameter is non-numeric, this method returns null.

The return value should be of the class type appropriate for the parameter's type, that is, Byte for a byte parameter, Integer for an int parameter, and so forth.

The default implementation returns the maximum value in the parameter data type's full range.

**Specified by:**

getParamMaxValue in interface OperationDescriptor

**Parameters:**

index - The index of the parameter to be queried.

**Returns:**

A Number representing the maximum legal value, or null if the specified parameter is not numeric.

**Throws:**

NullPointerException - if this operation has no parameters.

ArrayIndexOutOfBoundsException - if there is no parameter corresponding to the specified index.

---

## validateSources

```
protected boolean validateSources(java.awt.image.renderable.ParameterBlock args,  
                                 java.lang.StringBuffer msg)
```

Returns true if this operation supports the rendered mode, and is capable of handling the input source(s) for the rendered mode. The default implementation validates the number of sources, the class type of each source, and null source. Subclasses should override this implementation if their requirement on the sources are different from the default.

**Throws:**

NullPointerException - if args is null.

NullPointerException - if msg is null and the validation fails.

---

## validateRenderableSources

```
protected boolean validateRenderableSources(java.awt.image.renderable.ParameterBlock args,  
                                             java.lang.StringBuffer msg)
```

Returns true if this operation supports the renderable mode, and is capable of handling the input source(s) for the renderable mode. The default implementation validates the number of sources, the class type of each source, and null source. Subclasses should override this implementation if their requirement on the sources are different from the default.

**Throws:**

NullPointerException - if args is null.  
NullPointerException - if msg is null and the validation fails.

---

**validateSources**

```
private boolean validateSources(java.lang.Class[] sources,  
                               java.awt.image.renderable.ParameterBlock args,  
                               java.lang.StringBuffer msg)
```

Validates sources in the ParameterBlock against the sources of the specification.

**Throws:**

NullPointerException - if args is null.  
NullPointerException - if msg is null and the validation fails.

---

**validateParameters**

```
protected boolean validateParameters(java.awt.image.renderable.ParameterBlock args,  
                                     java.lang.StringBuffer msg)
```

Returns true if this operation is capable of handling the input parameters. The default implementation validates the number of parameters, the class type of each parameter, and null parameter. For those non-null numeric parameters, it also checks to see if the parameter value is within the minimum and maximum parameter range. Subclasses should override this implementation if their requirement on the parameter objects are different from the default.

JAI allows unspecified trailing parameters if these parameters have default values. This method automatically sets these unspecified parameters to their default values. However, if a parameter, who has a default value, is followed by one or more parameters that have no default values, this parameter must be specified in the ParameterBlock; else this method returns false.

**Throws:**

NullPointerException - if args is null.  
NullPointerException - if msg is null and the validation fails.

---

**getMinNumParameters**

```
private int getMinNumParameters()
```

Returns the minimum number of parameters must be supplied in the ParameterBlock.

---

**createFormatter**

```
private java.text.MessageFormat createFormatter(java.lang.String msg)
```

Creates a MessageFormat object and set the Locale to default.

---

## javax.media.jai Class OperationGraph

```
java.lang.Object
|
+-- javax.media.jai.OperationGraph
```

---

class **OperationGraph**  
extends java.lang.Object

OperationGraph manages a list of products belonging to a particular operation descriptor. The operations have pairwise preferences between them. The `getOrderedOperationList` method performs a topological sort. The topological sort follows the algorithm described in Horowitz and Sahni, *Fundamentals of Data Structures* (1976), p. 315.

Several minor changes are made to their implementation. First, nodes are represented as objects, not as integers. The count (in-degree) field is not used to link zero in-degree objects, but instead a separate `zeroLink` field is used. The neighbor lists are stored as Vectors, not linked lists, and enumerations are used to iterate over them.

This class is used by the implementation of the `OperationRegistry` class and is not intended to be part of the API.

---

### Field Detail

#### RIFoperations

protected java.util.Vector **RIFoperations**  
A Vector of RIF implementations.

---

#### CIFoperations

protected java.util.Vector **CIFoperations**  
A Vector of CIF implementations.

---

#### orderedRIFoperations

protected java.util.Vector **orderedRIFoperations**  
The cached list of ordered operations for RIF/CIF

---

#### orderedCIFoperations

protected java.util.Vector **orderedCIFoperations**

---

#### isRIFChanged

protected boolean **isRIFChanged**

---

#### isCIFChanged

protected boolean **isCIFChanged**

---

#### lock

com.sun.media.jai.util.ReaderWriterLock **lock**

---

### Constructor Detail

#### OperationGraph

public **OperationGraph()**  
Constructs an OperationGraph.

---

### Method Detail

---

### **addRIF**

```
public void addRIF(java.awt.image.renderable.RenderedImageFactory rif)
```

Adds a RIF to an OperationGraph. A new PartialOrderNode is constructed to hold the RIF and its graph adjacency information.

---

### **addCIF**

```
public void addCIF(CollectionImageFactory cif)
```

Adds a CIF to an OperationGraph. A new PartialOrderNode is constructed to hold the CIF and its graph adjacency information.

---

### **removeRIF**

```
public void removeRIF(java.awt.image.renderable.RenderedImageFactory rif)
```

Removes a RIF from an OperationGraph.

---

### **removeCIF**

```
public void removeCIF(CollectionImageFactory cif)
```

Removes a CIF from an OperationGraph.

---

### **lookupRIF**

```
public PartialOrderNode lookupRIF(java.awt.image.renderable.RenderedImageFactory op)
```

Locates a RIF within the vector of PartialOrderNodes. Equality is by object reference. NOTE: CHANGING access from private to public

---

### **lookupCIF**

```
public PartialOrderNode lookupCIF(CollectionImageFactory op)
```

Locates a CIF within the vector of PartialOrderNodes. Equality is by object reference. NOTE: CHANGING access from private to public

---

### **setRIFPreference**

```
public void setRIFPreference(java.awt.image.renderable.RenderedImageFactory preferredOp,  
                             java.awt.image.renderable.RenderedImageFactory otherOp)
```

Sets a preference between two RIFs.

---

### **unsetRIFPreference**

```
public void unsetRIFPreference(java.awt.image.renderable.RenderedImageFactory preferredOp,  
                               java.awt.image.renderable.RenderedImageFactory otherOp)
```

Removes a preference between two RIFs.

---

### **setCIFPreference**

```
public void setCIFPreference(CollectionImageFactory preferredOp,  
                             CollectionImageFactory otherOp)
```

Sets a preference between two CIFs.

---

### **unsetCIFPreference**

```
public void unsetCIFPreference(CollectionImageFactory preferredOp,  
                               CollectionImageFactory otherOp)
```

Removes a preference between two CIFs.

---

## **getOrderedOperationList**

`public java.util.Vector getOrderedOperationList(java.lang.String imageFactory)`

Returns an ordered list of the specified imageFactory

---

## **orderList**

`private java.util.Vector orderList(java.util.Vector operations)`

Performs a topological sort on the set of image factories.

---

## javax.media.jai Class OperationRegistry

java.lang.Object  
|-- javax.media.jai.OperationRegistry

---

public class **OperationRegistry**  
extends java.lang.Object  
implements java.io.Externalizable

A class implementing the translation of operation names into instances of RenderedImageFactory, ContextualRenderedImageFactory and CollectionImageFactory.

The OperationRegistry class maps an operation name into the particular kind of ImageFactory requested, capable of implementing the operation, given a specific set of sources and parameters. The mapping is constructed in several stages:

One or more OperationDescriptors are registered by calling registerOperationDescriptor(). Once an OperationDescriptor has been registered, it may be obtained by name by calling getOperationDescriptor(). It is not possible to register more than one OperationDescriptor under the same name.

A set of RenderedImageFactory objects are registered using the registerRIF method. Each RIF is registered with a specific operation name, and furthermore is given a product name. Similar methods exist for registering a CIF.

A single CRIF is registered under a specific operation name using the registerCRIF method. If multiple CRIFs are registered under the same operation name, the one registered last will be the one honored. Since only a single CRIF is registered under an operation name, no ordering of CRIFs is possible. Thus product preferences do not have any effect on the selection of a CRIF, and preferences amongst CRIFs cannot be set.

The ordering of RIFs is determined by the order of the products attached to an OperationDescriptor, and the order of the RIFs within each product. The orders are established by setting pairwise preferences, resulting in a partial order which is then sorted topologically. The results of creating a cycle are undefined.

The ordering of RIFs within a product is intended to allow vendors to create complex "fallback" chains. An example would be installing a RIF that implements separable convolution ahead of a RIF that implements a more general algorithm.

The ordering of CIFs is managed in a manner identical to the RIFs.

Vendors are encouraged to use unique product names (by means of the Java programming language convention of reversed internet addresses) in order to maximize the likelihood of clean installation. See *The Java Programming Language*, §10.1 for a discussion of this convention in the context of package naming.

Users will, for the most part, only wish to set ordering preferences on the product level, since the RIF/CIF orderings will be complex. However, it is possible for a knowledgeable user to insert a RIF/CIF into an existing product for tuning purposes.

The registry handles all names (except class names) in a case-insensitive manner.

The OperationRegistry also has the responsibility of associating a set of PropertyGenerators with each OperationDescriptor. This set will be coalesced into a PropertySource suitable for use by a RenderedOp by the getPropertySource() method. If several PropertyGenerators associated with a particular OperationDescriptor generate the same property, only the last one to be registered will have any effect.

---

### Field Detail

#### opDescsName

java.util.Hashtable **opDescsName**

A Hashtable of all the OperationDescriptors, hashed by the operation name of the OperationDescriptors.

---

#### products

java.util.Hashtable **products**

A Hashtable of all the products, hashed by the operation name of the OperationDescriptor to which they belong.

---

#### rifs

java.util.Hashtable **rifs**

A Hashtable of all the RIFs, hashed by a filename that uniquely identifies each registered RIF.

---

## **rifsByName**

java.util.Hashtable **rifsByName**

A Hashtable of all the unique RIF filenames, hashed by the RIF they represent.

---

## **rifcount**

int **rifcount**

A count to give a number to each registered RIF.

---

## **cifs**

java.util.Hashtable **cifs**

Same as above three structures, but for CIFS.

---

## **cifsByName**

java.util.Hashtable **cifsByName**

---

## **cifcount**

int **cifcount**

---

## **crifs**

java.util.Hashtable **crifs**

Hashtable of all the crifs, hashed by the operationName to which they belong.

---

## **productPrefs**

java.util.Hashtable **productPrefs**

A Hashtable of all the product preferences, hashed by the operation name descriptor that the products belong to.

---

## **rifPrefs**

java.util.Hashtable **rifPrefs**

A Hashtable of all the RIF preferences, hashed by the operation name that the RIF belongs to.

---

## **cifPrefs**

java.util.Hashtable **cifPrefs**

A Hashtable of all the CIF preferences, hashed by the operation name that the CIF belongs to.

---

## **properties**

protected java.util.Hashtable **properties**

---

## **suppressed**

protected java.util.Hashtable **suppressed**

---

## **sourceForProp**

protected java.util.Hashtable **sourceForProp**

---

## propNames

protected java.util.Hashtable **propNames**

---

## formatter

private static java.text.MessageFormat **formatter**

Required to I18N compound messages.

---

## lock

private com.sun.media.jai.util.ReaderWriterLock **lock**

The ReaderWriter Lock for this class.

---

## Constructor Detail

### OperationRegistry

public **OperationRegistry**()

Default Constructor.

---

## Method Detail

### initializeRegistry

static OperationRegistry **initializeRegistry**()

Initializes the default registry, creating it if necessary.

**Returns:**

the default OperationRegistry

---

### readInitFile

private static RegistryInitData **readInitFile**(java.io.Reader reader)  
throws java.io.IOException

Reads the registry initialization file and stores the information read into memory data structures.

**Parameters:**

reader - A Reader stream used to read initialization data from.

**Returns:**

In memory initialization data.

---

### loadDescriptors

private void **loadDescriptors**(RegistryInitData rid)

A method for registry initialization.

**Parameters:**

rid - The in-memory initialization data.

---

### registerOperationDescriptorNoLock

private void **registerOperationDescriptorNoLock**(OperationDescriptor odesc,  
java.lang.String operationName)

---

### registerRIFNoLock

private void **registerRIFNoLock**(java.lang.String operationName,  
java.lang.String productName,  
java.awt.image.renderable.RenderedImageFactory RIF)

---

### registerCRIFNoLock

```
private void registerCRIFNoLock(java.lang.String operationName,  
                                java.awt.image.renderable.ContextualRenderedImageFactory CRIF)
```

---

### registerCIFNoLock

```
private void registerCIFNoLock(java.lang.String operationName,  
                                java.lang.String productName,  
                                CollectionImageFactory CIF)
```

---

### setProductPreferenceNoLock

```
private void setProductPreferenceNoLock(java.lang.String operationName,  
                                         java.lang.String preferredProductName,  
                                         java.lang.String otherProductName)
```

---

### setRIFPreferenceNoLock

```
private void setRIFPreferenceNoLock(java.lang.String operationName,  
                                     java.lang.String productName,  
                                     java.awt.image.renderable.RenderedImageFactory preferredRIF,  
                                     java.awt.image.renderable.RenderedImageFactory otherRIF)
```

---

### setCIFPreferenceNoLock

```
private void setCIFPreferenceNoLock(java.lang.String operationName,  
                                     java.lang.String productName,  
                                     CollectionImageFactory preferredCIF,  
                                     CollectionImageFactory otherCIF)
```

---

### toString

```
public java.lang.String toString()  
    Returns a String representation of the registry.  
Returns:  
    the string representation of this OperationRegistry.  
Overrides:  
    toString in class java.lang.Object
```

---

### writeToStream

```
public void writeToStream(java.io.OutputStream out)  
    throws java.io.IOException  
    Writes out the contents of the OperationRegistry to a stream.  
Parameters:  
    out - The OutputStream to which the OperationRegistry state is written.  
Throws:  
    NullPointerException - if out is null.
```

---

### initializeFromStream

```
public void initializeFromStream(java.io.InputStream in)  
    throws java.io.IOException  
    Loads the contents of the OperationRegistry from an InputStream.  
Parameters:  
    in - The InputStream from which to read the data.  
Throws:  
    NullPointerException - if in is null.
```

---

## readExternal

```
public void readExternal(java.io.ObjectInput in)
    throws java.io.IOException,
           java.lang.ClassNotFoundException
```

Restores the contents of the registry from an ObjectInput which was previously written using the writeExternal method.

**Specified by:**

readExternal in interface java.io.Externalizable

**Parameters:**

in - An ObjectInput from which to read the data.

**Throws:**

NullPointerException - if in is null.

---

## writeExternal

```
public void writeExternal(java.io.ObjectOutput out)
    throws java.io.IOException
```

Saves the contents of the registry in the format described for the writeToStream method.

**Specified by:**

writeExternal in interface java.io.Externalizable

**Parameters:**

out - An ObjectOutput to which to write the data.

**Throws:**

NullPointerException - if out is null.

---

## registerOperationDescriptor

```
public void registerOperationDescriptor(OperationDescriptor odesc,
    java.lang.String operationName)
```

Registers an OperationDescriptor with the registry. Each operation must have an OperationDescriptor before registerRIF() may be called to add RIFs to the operation.

An OperationDescriptor cannot be registered under an operation name under which another OperationDescriptor was registered previously. If such an attempt is made, an error message will be printed.

**Parameters:**

odesc - an OperationDescriptor containing information about the operation.

operationName - the operation name as a String.

**Throws:**

NullPointerException - if odesc is null.

NullPointerException - if operationName is null.

---

## unregisterOperationDescriptor

```
public void unregisterOperationDescriptor(java.lang.String operationName)
```

Unregisters an OperationDescriptor from the registry. An error message will be printed if an attempt is made to unregister an OperationDescriptor that was not previously registered.

**Parameters:**

operationName - the operation name as a String.

**Throws:**

NullPointerException - if operationName is null.

NullPointerException - if any of the PropertyGenerators associated with the OperationDescriptor to be removed is null.

---

## getOperationDescriptor

```
public OperationDescriptor getOperationDescriptor(java.lang.String operationName)
```

Returns the OperationDescriptor that is currently registered under the given name, or null if none exists.

**Parameters:**

operationName - the String to be queried.

**Returns:**

an OperationDescriptor.

**Throws:**

NullPointerException - if operationName is null.

---

## getOperationDescriptors

```
public java.util.Vector getOperationDescriptors()
```

Returns a Vector of all currently registered OperationDescriptors.

**Returns:**  
a Vector of OperationDescriptors.

---

## getOperationNames

```
public java.lang.String[] getOperationNames()
```

Returns a list of names under which all the OperationDescriptors in the registry are registered.

**Returns:**  
a list of currently existing operation names.

---

## registerRIF

```
public void registerRIF(java.lang.String operationName,  
                        java.lang.String productName,  
                        java.awt.image.renderable.RenderedImageFactory RIF)
```

Registers a RIF with a particular product and operation. An error message will be printed out if the operation was not registered previously.

**Parameters:**  
operationName - the operation name as a String.  
productName - the product name, as a String.  
RIF - the RenderedImageFactory to be registered.

**Throws:**  
NullPointerException - if operationName is null.  
NullPointerException - if productName is null.  
NullPointerException - if RIF is null.

---

## unregisterRIF

```
public void unregisterRIF(java.lang.String operationName,  
                           java.lang.String productName,  
                           java.awt.image.renderable.RenderedImageFactory RIF)
```

Unregisters a RIF from a particular product and operation. An error message will be printed out if the operation was not registered previously or if the product has not been registered under the operation.

**Parameters:**  
operationName - the operation name as a String.  
productName - the product name, as a String.  
RIF - the RenderedImageFactory to be unregistered.

**Throws:**  
NullPointerException - if operationName is null.  
NullPointerException - if productName is null.  
NullPointerException - if RIF is null.

---

## registerCRIF

```
public void registerCRIF(java.lang.String operationName,  
                          java.awt.image.renderable.ContextualRenderedImageFactory CRIF)
```

Registers a CRIF under a particular operation. An error message will be printed out if the operation was not registered previously.

**Parameters:**  
operationName - the operation name as a String.  
CRIF - the ContextualRenderedImageFactory to be registered.

**Throws:**  
NullPointerException - if operationName is null.  
NullPointerException - if CRIF is null.

---

## unregisterCRIF

```
public void unregisterCRIF(java.lang.String operationName,  
                           java.awt.image.renderable.ContextualRenderedImageFactory CRIF)
```

Unregisters a CRIF from a particular operation. An error message will be printed out if the operation was not registered previously.

**Parameters:**

operationName - the operation name as a String.  
CRIF - the ContextualRenderedImageFactory to be unregistered.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if CRIF is null.

---

## registerCIF

```
public void registerCIF(java.lang.String operationName,  
                        java.lang.String productName,  
                        CollectionImageFactory CIF)
```

Registers a CIF with a particular product and operation. An error message will be printed out if the operation was not registered previously.

**Parameters:**

operationName - the operation name as a String.  
productName - the product name, as a String.  
CIF - the CollectionImageFactory to be registered.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if productName is null.  
NullPointerException - if CIF is null.

---

## unregisterCIF

```
public void unregisterCIF(java.lang.String operationName,  
                           java.lang.String productName,  
                           CollectionImageFactory CIF)
```

Unregisters a CIF from a particular product and operation. An error message will be printed out if the operation was not registered previously or if the product was not registered under the operation previously.

**Parameters:**

operationName - the operation name as a String.  
productName - the product name, as a String.  
CIF - the CollectionImageFactory to be unregistered.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if productName is null.  
NullPointerException - if CIF is null.

---

## setProductPreference

```
public void setProductPreference(java.lang.String operationName,  
                                  java.lang.String preferredProductName,  
                                  java.lang.String otherProductName)
```

Sets a preference between two products registered under a common OperationDescriptor. An error will be printed out if the operation was not registered previously and no preference will be set. Any attempt to set a preference between a product and itself will be ignored.

**Parameters:**

operationName - the operation name as a String.  
preferredProductName - the product to be preferred.  
otherProductName - the other product.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if preferredProductName is null.  
NullPointerException - if otherProductName is null.

---

## unsetProductPreference

```
public void unsetProductPreference(java.lang.String operationName,  
                                   java.lang.String preferredProductName,  
                                   java.lang.String otherProductName)
```

Removes a preference between two products registered under a common OperationDescriptor. An error message will be printed out if the operation was not registered previously.

**Parameters:**

operationName - the operation name as a String.  
preferredProductName - the product formerly preferred.  
otherProductName - the other product.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if preferredProductName is null.  
NullPointerException - if otherProductName is null.

---

## clearProductPreferences

```
public void clearProductPreferences(java.lang.String operationName)
```

Removes all preferences between products registered under a common OperationDescriptor. An error message will be printed out if the operation was not registered previously.

**Parameters:**

operationName - the operation name as a String.

**Throws:**

NullPointerException - if operationName is null.

---

## getProductPreferences

```
public java.lang.String[][] getProductPreferences(java.lang.String operationName)
```

Returns a list of the pairwise product preferences under a particular OperationDescriptor. If no product preferences have been set, returns null.

**Parameters:**

operationName - the operation name as a String.

**Returns:**

an array of 2-element arrays of Strings.

**Throws:**

NullPointerException - if operationName is null.

---

## getOrderedProductList

```
public java.util.Vector getOrderedProductList(java.lang.String operationName)
```

Returns a list of the products registered under a particular OperationDescriptor, in an ordering that satisfies all of the pairwise preferences that have been set. Cycles will be broken in an arbitrary manner. Returns null if no OperationDescriptor has been registered under this operationName, or if no products exist for this operation.

**Parameters:**

operationName - the operation name as a String.

**Returns:**

a Vector of Strings representing product names.

**Throws:**

NullPointerException - if operationName is null.

---

## setRIFPreference

```
public void setRIFPreference(java.lang.String operationName,  
                             java.lang.String productName,  
                             java.awt.image.renderable.RenderedImageFactory preferredRIF,  
                             java.awt.image.renderable.RenderedImageFactory otherRIF)
```

Sets a preference between two RIFs within the same product. An error message will be printed out if the operation was not registered previously or if the product was not registered under the operation or if either of the supplied RIFs is null. Any attempt to set a preference between a RIF and itself will be ignored.

**Parameters:**

operationName - the operation name as a String.  
productName - the name of the product.  
preferredRIF - the preferred RenderedImageFactory.  
otherRIF - the other RenderedImageFactory.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if productName is null.  
NullPointerException - if preferredRIF is null.  
NullPointerException - if otherRIF is null.

---

**setCIFPreference**

```
public void setCIFPreference(java.lang.String operationName,  
                             java.lang.String productName,  
                             CollectionImageFactory preferredCIF,  
                             CollectionImageFactory otherCIF)
```

Sets a preference between two CIFs within the same product. An error message will be printed out if the operation was not registered previously or if the product was not registered under the operation or if either of the two supplied CIF's is null. Any attempt to set a preference between a CIF and itself will be ignored.

**Parameters:**

operationName - the operation name as a String.  
productName - the name of the product.  
preferredCIF - the preferred CollectionRenderedImageFactory.  
otherCIF - the other CollectionRenderedImageFactory.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if productName is null.  
NullPointerException - if preferredCIF is null.  
NullPointerException - if otherCIF is null.

---

**unsetRIFPreference**

```
public void unsetRIFPreference(java.lang.String operationName,  
                               java.lang.String productName,  
                               java.awt.image.renderable.RenderedImageFactory preferredRIF,  
                               java.awt.image.renderable.RenderedImageFactory otherRIF)
```

Removes a preference between two RIFs within the same product. An error message will be printed out if the operation was not registered previously or if the product was not registered under the operation or if either of the two supplied RIF's is null.

**Parameters:**

operationName - the operation name as a String.  
productName - the name of the product.  
preferredRIF - the formerly preferred RenderedImageFactory.  
otherRIF - the other RenderedImageFactory.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if productName is null.  
NullPointerException - if preferredRIF is null.  
NullPointerException - if otherRIF is null.

---

**unsetCIFPreference**

```
public void unsetCIFPreference(java.lang.String operationName,  
                               java.lang.String productName,  
                               CollectionImageFactory preferredCIF,  
                               CollectionImageFactory otherCIF)
```

Removes a preference between two CIFs within the same product. An error message will be printed out if the operation was not registered previously or if the product was not registered under the operation or if either of the two supplied CIF's is null.

**Parameters:**

operationName - the operation name as a String.  
productName - the name of the product.  
preferredCIF - the formerly preferred CollectionImageFactory.  
otherCIF - the other CollectionImageFactory.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if productName is null.  
NullPointerException - if preferredCIF is null.  
NullPointerException - if otherCIF is null.

---

## clearRIFPreferences

```
public void clearRIFPreferences(java.lang.String operationName,  
                               java.lang.String productName)
```

Removes all preferences between RIFs within a product registered under a particular OperationDescriptor. An error message will be printed out if the operation was not registered previously or if the product was not registered under the operation.

**Parameters:**

operationName - the operation name as a String.  
productName - the name of the product.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if productName is null.

---

## clearCIFPreferences

```
public void clearCIFPreferences(java.lang.String operationName,  
                               java.lang.String productName)
```

Removes all preferences between CIFs within a product registered under a particular OperationDescriptor. An error message will be printed out if the operation was not registered previously or if the product was not registered under the operation.

**Parameters:**

operationName - the operation name as a String.  
productName - the name of the product.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if productName is null.

---

## clearOperationPreferences

```
public void clearOperationPreferences(java.lang.String operationName,  
                                     java.lang.String productName)
```

Removes all RIF and CIF preferences within a product registered under a particular OperationDescriptor.

**Parameters:**

operationName - the operation name as a String.  
productName - the name of the product.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if productName is null.

---

## getOrderedRIFList

```
public java.util.Vector getOrderedRIFList(java.lang.String operationName,  
                                          java.lang.String productName)
```

Returns a list of the RIFs of a product registered under a particular OperationDescriptor, in an ordering that satisfies all of the pairwise preferences that have been set. Cycles will be broken in an arbitrary manner. Returns null, if the product does not exist under this operationName.

**Parameters:**

operationName - the operation name as a String.  
productName - the name of the product.

**Returns:**

a Vector of RIFs.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if productName is null.

---

## getOrderedCIFList

```
public java.util.Vector getOrderedCIFList(java.lang.String operationName,  
                                          java.lang.String productName)
```

Returns a list of the CIFs of a product registered under a particular OperationDescriptor, in an ordering that satisfies all of the pairwise preferences that have been set. Cycles will be broken in an arbitrary manner. Returns null, if the product does not exist under this operationName.

**Parameters:**

operationName - the operation name as a String.  
productName - the name of the product.

**Returns:**

a Vector of CIFs.

**Throws:**

NullPointerException - if operationName is null.

NullPointerException - if productName is null.

---

**create**

```
public PlanarImage create(java.lang.String operationName,  
                           java.awt.image.renderable.ParameterBlock paramBlock,  
                           java.awt.RenderingHints renderHints)
```

Constructs a PlanarImage (usually a RenderedOp) representing the results of applying a given operation to a particular ParameterBlock and rendering hints. The registry is used to determine the RIF to be used to instantiate the operation.

If none of the RIFs registered with this OperationRegistry returns a non-null value, null is returned. Exceptions thrown by the RIFs will be caught by this method and will not be propagated.

**Parameters:**

operationName - the operation name as a String.

paramBlock - the operation's ParameterBlock.

renderHints - a RenderingHints object containing rendering hints.

**Throws:**

NullPointerException - if operationName is null.

---

**createRenderable**

```
public java.awt.image.renderable.ContextualRenderedImageFactory createRenderable(java.lang.String operationName,  
                                                                                   java.awt.image.renderable.ParameterBlock paramBlock)
```

Constructs the CRIF to be used to instantiate the operation. Returns null, if no CRIF is registered with the given operation name.

**Parameters:**

operationName - the operation name as a String.

paramBlock - the operation's ParameterBlock.

**Throws:**

NullPointerException - if operationName is null.

---

**createCollection**

```
public CollectionImage createCollection(java.lang.String operationName,  
                                          java.awt.image.renderable.ParameterBlock args,  
                                          java.awt.RenderingHints hints)
```

Constructs a CollectionImage (usually a CollectionOp) representing the results of applying a given operation to a particular ParameterBlock and rendering hints. The registry is used to determine the CIF to be used to instantiate the operation.

If none of the CIFs registered with this OperationRegistry returns a non-null value, null is returned. Exceptions thrown by the CIFs will be caught by this method and will not be propagated.

**Parameters:**

operationName - The operation name as a String.

args - The operation's input parameters.

hints - A RenderingHints object containing rendering hints.

**Throws:**

NullPointerException - if operationName is null.

---

**clearPropertyState**

```
public void clearPropertyState()
```

Removes all property associated information from this OperationRegistry.

---

**addPropertyGenerator**

```
public void addPropertyGenerator(java.lang.String operationName,  
                                  PropertyGenerator generator)
```

Adds a PropertyGenerator to the registry, associating it with a particular OperationDescriptor.

**Parameters:**

operationName - the operation name as a String.

generator - the PropertyGenerator to be added.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if generator is null.

---

**hashNames**

```
private void hashNames(java.lang.String operationName)
```

---

**removePropertyGenerator**

```
public void removePropertyGenerator(java.lang.String operationName,  
                                     PropertyGenerator generator)
```

Removes a PropertyGenerator from its association with a particular OperationDescriptor in the registry. If the generator was not associated with the operation, nothing happens.

**Parameters:**

operationName - the operation name as a String.  
generator - the PropertyGenerator to be removed.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if generator is null.

---

**suppressProperty**

```
public void suppressProperty(java.lang.String operationName,  
                             java.lang.String propertyName)
```

Forces a particular property to be suppressed by nodes performing a particular operation. By default, properties are passed through operations unchanged.

**Parameters:**

operationName - the operation name as a String.  
propertyName - the name of the property to be suppressed.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if propertyName is null.

---

**suppressAllProperties**

```
public void suppressAllProperties(java.lang.String operationName)
```

Forces all properties to be suppressed by nodes performing a particular operation. By default, properties are passed through operations unchanged.

**Parameters:**

operationName - the operation name as a String.

**Throws:**

NullPointerException - if operationName is null.

---

**copyPropertyFromSource**

```
public void copyPropertyFromSource(java.lang.String operationName,  
                                   java.lang.String propertyName,  
                                   int sourceIndex)
```

Forces a property to be copied from the specified source image by RenderedOp nodes performing a particular operation. By default, a property is copied from the first source node that emits it. The result of specifying an invalid source is undefined.

**Parameters:**

operationName - the operation name as a String.  
propertyName - the name of the property to be copied.  
sourceIndex - the index of the source to copy the property from.

**Throws:**

NullPointerException - if operationName is null.  
NullPointerException - if propertyName is null.

---

## **getGeneratedPropertyNames**

```
public java.lang.String[] getGeneratedPropertyNames(java.lang.String operationName)
```

Returns a list of the properties generated by nodes implementing the operation associated with a particular Operation Name. Returns null if no properties are generated.

**Parameters:**

operationName - the operation name as a String.

**Returns:**

an array of Strings.

**Throws:**

NullPointerException - if operationName is null.

---

## **getPropertySource**

```
public PropertySource getPropertySource(RenderedOp op)
```

Constructs and returns a PropertySource suitable for use by a given RenderedOp. The PropertySource includes properties copied from prior nodes as well as those generated at the node itself. Additionally, property suppression is taken into account. The actual implementation of getPropertySource() may make use of deferred execution and caching.

**Parameters:**

op - the RenderedOp requesting its PropertySource.

**Throws:**

NullPointerException - if op is null.

---

## **getPropertySource**

```
public PropertySource getPropertySource(RenderableOp op)
```

Constructs and returns a PropertySource suitable for use by a given RenderableOp. The PropertySource includes properties copied from prior nodes as well as those generated at the node itself. Additionally, property suppression is taken into account. The actual implementation of getPropertySource() may make use of deferred execution and caching.

**Parameters:**

op - the RenderableOp requesting its PropertySource.

---

## javax.media.jai Class ParameterBlockJAI

```
java.lang.Object
|
+--java.awt.image.renderable.ParameterBlock
|
+--javax.media.jai.ParameterBlockJAI
```

---

### public class **ParameterBlockJAI**

extends java.awt.image.renderable.ParameterBlock

A convenience subclass of ParameterBlock that allows the use of default parameter values and getting/setting parameters by name. A ParameterBlockJAI is constructed using either an OperationDescriptor, or an operation name that will be looked up in the appropriate (rendered or renderable) default OperationRegistry.

Once constructed, a ParameterBlockJAI appears to have no sources. It contains all the parameters required by its OperationDescriptor, each having its default value as given by the OperationDescriptor. Such a ParameterBlockJAI may not yet be usable, its sources (if any) are not set, and some or all of its parameters may have inappropriate values. The addSource methods of ParameterBlock may be used to set the source values, and the set(value, index) methods may be used to insert new parameter values. The add() methods should not be used since the parameter list is already long enough to hold all of the parameters required by the OperationDescriptor.

Additionally, ParameterBlockJAI offers set(value, name) methods that take a parameter name; the index of the parameter is determined from the OperationDescriptor and the corresponding parameter is set. As in ParameterBlock, all parameters are stored internally as subclasses of Object and all get/set methods that take or return values of base types are simply conveniences that transform values between the base types and their corresponding Number subclasses.

---

## Field Detail

### odesc

private OperationDescriptor **odesc**

The OperationDescriptor associated with this ParameterBlockJAI.

---

### paramClasses

private java.lang.Class[] **paramClasses**

The Class types of the parameters.

---

### indexTable

private java.util.Hashtable **indexTable**

A Hashtable mapping parameter names to their index.

---

## Constructor Detail

### ParameterBlockJAI

public **ParameterBlockJAI**(OperationDescriptor odesc)

Constructs a ParameterBlockJAI for use with an operation described by a particular OperationDescriptor. The default values of the parameters are filled in.

---

### ParameterBlockJAI

public **ParameterBlockJAI**(java.lang.String name)

Constructs a ParameterBlockJAI for a particular operation by name. The OperationRegistry associated with the default instance of the JAI class is used to locate the OperationDescriptor associated with the operation name.

#### Parameters:

name - a String giving the name of the operation.

---

## Method Detail

## indexOf

```
public int indexOf(java.lang.String paramName)
```

Returns the index of a named parameter within the list of parameters, starting with 0.

**Parameters:**

paramName - a String containing the parameter name.

---

## getOperationDescriptor

```
public OperationDescriptor getOperationDescriptor()
```

Returns the OperationDescriptor associated with this ParameterBlockJAI.

---

## set

```
public java.awt.image.renderable.ParameterBlock set(byte b,  
                                                    java.lang.String paramName)
```

Sets a named parameter to a byte value.

**Parameters:**

paramName - a String naming a parameter.  
b - a byte value for the parameter.

---

## set

```
public java.awt.image.renderable.ParameterBlock set(char c,  
                                                    java.lang.String paramName)
```

Sets a named parameter to a char value.

**Parameters:**

paramName - a String naming a parameter.  
c - a char value for the parameter.

---

## set

```
public java.awt.image.renderable.ParameterBlock set(short s,  
                                                    java.lang.String paramName)
```

Sets a named parameter to a short value.

**Parameters:**

paramName - a String naming a parameter.  
s - a short value for the parameter.

---

## set

```
public java.awt.image.renderable.ParameterBlock set(int i,  
                                                    java.lang.String paramName)
```

Sets a named parameter to an int value.

**Parameters:**

paramName - a String naming a parameter.  
i - an int value for the parameter.

---

## set

```
public java.awt.image.renderable.ParameterBlock set(long l,  
                                                    java.lang.String paramName)
```

Sets a named parameter to a long value.

**Parameters:**

paramName - a String naming a parameter.  
l - a long value for the parameter.

---

### **set**

```
public java.awt.image.renderable.ParameterBlock set(float f,  
                                                    java.lang.String paramName)
```

Sets a named parameter to a float value.

**Parameters:**

paramName - a String naming a parameter.  
f - a float value for the parameter.

---

### **set**

```
public java.awt.image.renderable.ParameterBlock set(double d,  
                                                    java.lang.String paramName)
```

Sets a named parameter to a double value.

**Parameters:**

paramName - a String naming a parameter.  
d - a double value for the parameter.

---

### **set**

```
public java.awt.image.renderable.ParameterBlock set(java.lang.Object obj,  
                                                    java.lang.String paramName)
```

Sets a named parameter to an Object value.

**Parameters:**

paramName - a String naming a parameter.  
obj - an Object value for the parameter.

---

### **getObjectParameter**

```
public java.lang.Object getObjectParameter(java.lang.String paramName)
```

Gets a named parameter as an Object. Parameters belonging to a base type, such as int, will be returned as a member of the corresponding Number subclass, such as Integer.

---

### **getBytesParameter**

```
public byte getBytesParameter(java.lang.String paramName)
```

A convenience method to return a parameter as a byte. An exception will be thrown if the parameter is of a different type.

**Parameters:**

paramName - the name of the parameter to be returned.

---

### **getCharParameter**

```
public char getCharParameter(java.lang.String paramName)
```

A convenience method to return a parameter as a char. An exception will be thrown if the parameter is of a different type.

**Parameters:**

paramName - the name of the parameter to be returned.

---

### **getIntParameter**

```
public int getIntParameter(java.lang.String paramName)
```

A convenience method to return a parameter as an int. An exception will be thrown if the parameter is of a different type.

**Parameters:**

paramName - the name of the parameter to be returned.

---

### **getLongParameter**

```
public long getLongParameter(java.lang.String paramName)
```

A convenience method to return a parameter as a long. An exception will be thrown if the parameter is of a different type.

**Parameters:**

paramName - the name of the parameter to be returned.

---

### **getFloatParameter**

public float **getFloatParameter**(java.lang.String paramName)

A convenience method to return a parameter as a float. An exception will be thrown if the parameter is of a different type.

**Parameters:**

paramName - the name of the parameter to be returned.

---

### **getDoubleParameter**

public double **getDoubleParameter**(java.lang.String paramName)

A convenience method to return a parameter as a double. An exception will be thrown if the parameter is of a different type.

**Parameters:**

paramName - the name of the parameter to be returned.

---

## javax.media.jai Class PartialOrderNode

```
java.lang.Object
|
+-- javax.media.jai.PartialOrderNode
```

---

### class PartialOrderNode

extends java.lang.Object  
implements java.lang.Cloneable, java.io.Serializable

A node in a directed graph of operations. Each node maintains three pieces of information, in addition to an arbitrary Object containing user data associated with the node, in order to allow topological sorting to be performed in linear time.

First, the in-degree (number of other nodes pointing to this node) is stored as an int. Nodes with in-degree equal to 0 are "free" and may appear first in a topological sort.

Second, a reference called zeroLink to another PartialOrderNode is kept in order to allow construction of a linked list of nodes with zero in-degree.

Third, a Vector of neighboring nodes is maintained (in no particular order). These are the nodes which are pointed to by the current node.

This class is used by the implementation of the OperationRegistry class and is not intended to be part of the API.

---

### Field Detail

#### name

protected java.lang.String **name**

The name of the object associated with this node.

---

#### nodeData

protected java.lang.Object **nodeData**

The data associated with this node.

---

#### inDegree

protected int **inDegree**

The in-degree of the node.

---

#### copyInDegree

protected int **copyInDegree**

Copy of the inDegree of the node.

---

#### zeroLink

protected PartialOrderNode **zeroLink**

A link to another node with 0 in-degree, or null.

---

#### neighbors

java.util.Vector **neighbors**

A Vector of neighboring nodes.

---

### Constructor Detail

---

## PartialOrderNode

```
public PartialOrderNode(java.lang.Object nodeData,  
                        java.lang.String name)
```

Constructs an PartialOrderNode with given associated data.

**Parameters:**

nodeData - an Object to associate with this node.

### Method Detail

#### getData

```
public java.lang.Object getData()
```

Returns the Object represented by this node.

#### getName

```
public java.lang.String getName()
```

Returns the name of the Object represented by this node.

#### getInDegree

```
public int getInDegree()
```

Returns the in-degree of this node.

#### getCopyInDegree

```
public int getCopyInDegree()
```

Returns the copy in-degree of this node.

#### setCopyInDegree

```
public void setCopyInDegree(int copyInDegree)
```

Sets the copy in-degree of this node.

#### getZeroLink

```
public PartialOrderNode getZeroLink()
```

Returns the next zero in-degree node in the linked list.

#### setZeroLink

```
public void setZeroLink(PartialOrderNode poNode)
```

Sets the next zero in-degree node in the linked list.

#### getNeighbors

```
public java.util.Enumeration getNeighbors()
```

Returns the neighbors of this node as an enumeration.

#### addEdge

```
public void addEdge(PartialOrderNode poNode)
```

Adds a directed edge to the graph. The neighbors list of this node is updated and the in-degree of the other node is incremented.

### **removeEdge**

```
public void removeEdge(PartialOrderNode poNode)
```

Removes a directed edge from the graph. The neighbors list of this node is updated and the in-degree of the other node is decremented.

---

### **incrementInDegree**

```
public void incrementInDegree()
```

Increments the in-degree of a node.

---

### **incrementCopyInDegree**

```
public void incrementCopyInDegree()
```

Increments the copy-in-degree of a node.

---

### **decrementInDegree**

```
public void decrementInDegree()
```

Decrements the in-degree of a node.

---

### **decrementCopyInDegree**

```
public void decrementCopyInDegree()
```

Decrements the copy in-degree of a node.

---

## javax.media.jai Class PerspectiveTransform

java.lang.Object  
|  
+-- javax.media.jai.PerspectiveTransform

---

public final class **PerspectiveTransform**

extends java.lang.Object

implements java.lang.Cloneable, java.io.Serializable

A 2D perspective (or projective) transform, used by various OpImages.

A perspective transformation is capable of mapping an arbitrary quadrilateral into another arbitrary quadrilateral, while preserving the straightness of lines. Unlike an affine transformation, the parallelism of lines in the source is not necessarily preserved in the output.

Such a coordinate transformation can be represented by a 3x3 matrix which transforms homogenous source coordinates ( $x$ ,  $y$ , 1) into destination coordinates ( $x'$ ,  $y'$ ,  $w$ ). To convert back into non-homogenous coordinates ( $X$ ,  $Y$ ),  $x'$  and  $y'$  are divided by  $w$ .

$$\begin{bmatrix} x' \\ y' \\ w \end{bmatrix} = \begin{bmatrix} m00 & m01 & m02 \\ m10 & m11 & m12 \\ m20 & m21 & m22 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = \begin{bmatrix} m00x + m01y + m02 \\ m10x + m11y + m12 \\ m20x + m21y + m22 \end{bmatrix}$$

$$x' = (m00x + m01y + m02) / (m20x + m21y + m22)$$

$$y' = (m10x + m11y + m12) / (m20x + m21y + m22)$$

$$X = x' / w$$

$$Y = y' / w$$

---

### Field Detail

#### PERSPECTIVE\_DIVIDE\_EPSILON

private static final double **PERSPECTIVE\_DIVIDE\_EPSILON**

---

#### m00

double **m00**

An element of the transform matrix.

---

#### m01

double **m01**

An element of the transform matrix.

---

#### m02

double **m02**

An element of the transform matrix.

---

#### m10

double **m10**

An element of the transform matrix.

---

#### m11

double **m11**

An element of the transform matrix.

---

## **m12**

double **m12**

An element of the transform matrix.

---

## **m20**

double **m20**

An element of the transform matrix.

---

## **m21**

double **m21**

An element of the transform matrix.

---

## **m22**

double **m22**

An element of the transform matrix.

## **Constructor Detail**

### **PerspectiveTransform**

public **PerspectiveTransform**()

Constructs an identity PerspectiveTransform.

---

### **PerspectiveTransform**

```
public PerspectiveTransform(float m00,  
                             float m01,  
                             float m02,  
                             float m10,  
                             float m11,  
                             float m12,  
                             float m20,  
                             float m21,  
                             float m22)
```

Constructs a new PerspectiveTransform from 9 floats.

---

### **PerspectiveTransform**

```
public PerspectiveTransform(double m00,  
                             double m01,  
                             double m02,  
                             double m10,  
                             double m11,  
                             double m12,  
                             double m20,  
                             double m21,  
                             double m22)
```

Constructs a new PerspectiveTransform from 9 doubles.

---

### **PerspectiveTransform**

public **PerspectiveTransform**(float[] flatmatrix)

Constructs a new PerspectiveTransform from a one-dimensional array of 9 floats, in row-major order. The values in the array are assumed to be { m00 m01 m02 m10 m11 m12 m20 m21 m22 }.

#### **Throws:**

NullPointerException - if flatmatrix is null

ArrayBoundsException - if flatmatrix is too small

---

## PerspectiveTransform

```
public PerspectiveTransform(float[][] matrix)
```

Constructs a new PerspectiveTransform from a two-dimensional array of floats.

**Throws:**

NullPointerException - if matrix is null

ArrayBoundsException - if matrix is too small

---

## PerspectiveTransform

```
public PerspectiveTransform(double[] flatmatrix)
```

Constructs a new PerspectiveTransform from a one-dimensional array of 9 doubles, in row-major order. The values in the array are assumed to be { m00 m01 m02 m10 m11 m12 m20 m21 m22 }.

**Throws:**

NullPointerException - if flatmatrix is null

ArrayBoundsException - if flatmatrix is too small

---

## PerspectiveTransform

```
public PerspectiveTransform(double[][] matrix)
```

Constructs a new PerspectiveTransform from a two-dimensional array of doubles.

**Throws:**

NullPointerException - if matrix is null

ArrayBoundsException - if matrix is too small

---

## PerspectiveTransform

```
public PerspectiveTransform(java.awt.geom.AffineTransform transform)
```

Constructs a new PerspectiveTransform with the same effect as an existing AffineTransform.

**Throws:**

NullPointerException - if transform is null

## Method Detail

### makeAdjoint

```
private final void makeAdjoint()
```

Replaces the matrix with its adjoint.

---

### normalize

```
private final void normalize()
```

Scales the matrix elements so m22 is equal to 1.0. m22 must not be equal to 0.

---

### getSquareToQuad

```
private static final void getSquareToQuad(double x0,  
                                           double y0,  
                                           double x1,  
                                           double y1,  
                                           double x2,  
                                           double y2,  
                                           double x3,  
                                           double y3,  
                                           PerspectiveTransform tx)
```

---

### getSquareToQuad

```
public static PerspectiveTransform getSquareToQuad(double x0,  
                                                    double y0,  
                                                    double x1,  
                                                    double y1,
```

```
double x2,  
double y2,  
double x3,  
double y3)
```

Creates a PerspectiveTransform that maps the unit square onto an arbitrary quadrilateral.

```
(0, 0) -> (x0, y0)  
(1, 0) -> (x1, y1)  
(1, 1) -> (x2, y2)  
(0, 1) -> (x3, y3)
```

---

## getSquareToQuad

```
public static PerspectiveTransform getSquareToQuad(float x0,  
float y0,  
float x1,  
float y1,  
float x2,  
float y2,  
float x3,  
float y3)
```

Creates a PerspectiveTransform that maps the unit square onto an arbitrary quadrilateral.

```
(0, 0) -> (x0, y0)  
(1, 0) -> (x1, y1)  
(1, 1) -> (x2, y2)  
(0, 1) -> (x3, y3)
```

---

## getQuadToSquare

```
public static PerspectiveTransform getQuadToSquare(double x0,  
double y0,  
double x1,  
double y1,  
double x2,  
double y2,  
double x3,  
double y3)
```

Creates a PerspectiveTransform that maps an arbitrary quadrilateral onto the unit square.

```
(x0, y0) -> (0, 0)  
(x1, y1) -> (1, 0)  
(x2, y2) -> (1, 1)  
(x3, y3) -> (0, 1)
```

---

## getQuadToSquare

```
public static PerspectiveTransform getQuadToSquare(float x0,  
float y0,  
float x1,  
float y1,  
float x2,  
float y2,  
float x3,  
float y3)
```

Creates a PerspectiveTransform that maps an arbitrary quadrilateral onto the unit square.

```
(x0, y0) -> (0, 0)  
(x1, y1) -> (1, 0)  
(x2, y2) -> (1, 1)  
(x3, y3) -> (0, 1)
```

---

## getQuadToQuad

```
public static PerspectiveTransform getQuadToQuad(double x0,  
double y0,  
double x1,  
double y1,  
double x2,  
double y2,  
double x3,  
double y3,  
double x0p,  
double y0p,
```

```
double x1p,  
double y1p,  
double x2p,  
double y2p,  
double x3p,  
double y3p)
```

Creates a PerspectiveTransform that maps an arbitrary quadrilateral onto another arbitrary quadrilateral.

```
(x0, y0) -> (x0p, y0p)  
(x1, y1) -> (x1p, y1p)  
(x2, y2) -> (x2p, y2p)  
(x3, y3) -> (x3p, y3p)
```

---

## getQuadToQuad

```
public static PerspectiveTransform getQuadToQuad(float x0,  
float y0,  
float x1,  
float y1,  
float x2,  
float y2,  
float x3,  
float y3,  
float x0p,  
float y0p,  
float x1p,  
float y1p,  
float x2p,  
float y2p,  
float x3p,  
float y3p)
```

Creates a PerspectiveTransform that maps an arbitrary quadrilateral onto another arbitrary quadrilateral.

```
(x0, y0) -> (x0p, y0p)  
(x1, y1) -> (x1p, y1p)  
(x2, y2) -> (x2p, y2p)  
(x3, y3) -> (x3p, y3p)
```

---

## getDeterminant

```
public double getDeterminant()
```

Returns the determinant of the matrix representation of the transform.

---

## getMatrix

```
public double[] getMatrix(double[] flatmatrix)
```

Retrieves the 9 specifiable values in the 3x3 affine transformation matrix into an array of double precision values. The values are stored into the array as { m00 m01 m02 m10 m11 m12 m20 m21 m22 }.

**Parameters:**

flatmatrix - The double array used to store the returned values. The length of the array is assumed to be at least 9.

**Throws:**

ArrayBoundsException - if flatmatrix is too small

---

## getMatrix

```
public double[][] getMatrix(double[][] matrix)
```

Retrieves the 9 specifiable values in the 3x3 affine transformation matrix into a 2-dimensional array of double precision values. The values are stored into the 2-dimensional array using the row index as the first subscript and the column index as the second.

**Parameters:**

matrix - The 2-dimensional double array to store the returned values. The array is assumed to be at least 3x3.

**Throws:**

ArrayBoundsException - if matrix is too small

---

## translate

```
public void translate(double tx,  
                     double ty)
```

Concatenates this transform with a translation transformation. This is equivalent to calling concatenate(T), where T is an PerspectiveTransform represented by the following matrix:

$$\begin{bmatrix} 1 & 0 & tx \\ 0 & 1 & ty \\ 0 & 0 & 1 \end{bmatrix}$$

---

## rotate

```
public void rotate(double theta)
```

Concatenates this transform with a rotation transformation. This is equivalent to calling concatenate(R), where R is an PerspectiveTransform represented by the following matrix:

$$\begin{bmatrix} \cos(\theta) & -\sin(\theta) & 0 \\ \sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Rotating with a positive angle theta rotates points on the positive X axis toward the positive Y axis.

**Parameters:**

theta - The angle of rotation in radians.

---

## rotate

```
public void rotate(double theta,  
                  double x,  
                  double y)
```

Concatenates this transform with a translated rotation transformation. This is equivalent to the following sequence of calls:

```
translate(x, y);  
rotate(theta);  
translate(-x, -y);
```

Rotating with a positive angle theta rotates points on the positive X axis toward the positive Y axis.

**Parameters:**

theta - The angle of rotation in radians.

x - The X coordinate of the origin of the rotation

y - The Y coordinate of the origin of the rotation

---

## scale

```
public void scale(double sx,  
                 double sy)
```

Concatenates this transform with a scaling transformation. This is equivalent to calling concatenate(S), where S is an PerspectiveTransform represented by the following matrix:

$$\begin{bmatrix} sx & 0 & 0 \\ 0 & sy & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

**Parameters:**

sx - The X axis scale factor.

sy - The Y axis scale factor.

---

## shear

```
public void shear(double shx,  
                 double shy)
```

Concatenates this transform with a shearing transformation. This is equivalent to calling concatenate(SH), where SH is an PerspectiveTransform represented by the following matrix:

$$\begin{bmatrix} 1 & shx & 0 \\ shy & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

**Parameters:**

shx - The factor by which coordinates are shifted towards the positive X axis direction according to their Y coordinate.

shy - The factor by which coordinates are shifted towards the positive Y axis direction according to their X coordinate.

---

## setToIdentity

```
public void setToIdentity()
```

Resets this transform to the Identity transform.

---

## setToTranslation

```
public void setToTranslation(double tx,  
                             double ty)
```

Sets this transform to a translation transformation. The matrix representing this transform becomes:

$$\begin{bmatrix} 1 & 0 & tx \\ 0 & 1 & ty \\ 0 & 0 & 1 \end{bmatrix}$$

**Parameters:**

tx - The distance by which coordinates are translated in the X axis direction

ty - The distance by which coordinates are translated in the Y axis direction

---

## setToRotation

```
public void setToRotation(double theta)
```

Sets this transform to a rotation transformation. The matrix representing this transform becomes:

$$\begin{bmatrix} \cos(\theta) & -\sin(\theta) & 0 \\ \sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Rotating with a positive angle theta rotates points on the positive X axis toward the positive Y axis.

**Parameters:**

theta - The angle of rotation in radians.

---

## setToRotation

```
public void setToRotation(double theta,  
                           double x,  
                           double y)
```

Sets this transform to a rotation transformation about a specified point (x, y). This is equivalent to the following sequence of calls:

```
setToTranslate(x, y);  
rotate(theta);  
translate(-x, -y);
```

Rotating with a positive angle theta rotates points on the positive X axis toward the positive Y axis.

**Parameters:**

theta - The angle of rotation in radians.

x - The X coordinate of the origin of the rotation

y - The Y coordinate of the origin of the rotation

---

## setToScale

```
public void setToScale(double sx,  
                       double sy)
```

Sets this transform to a scale transformation with scale factors sx and sy. The matrix representing this transform becomes:

$$\begin{bmatrix} sx & 0 & 0 \\ 0 & sy & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

**Parameters:**

sx - The X axis scale factor.

sy - The Y axis scale factor.

---

## setToShear

```
public void setToShear(double shx,  
                       double shy)
```

Sets this transform to a shearing transformation with shear factors sx and sy. The matrix representing this transform becomes:

$$\begin{bmatrix} 1 & shx & 0 \\ shy & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

**Parameters:**

shx - The factor by which coordinates are shifted towards the positive X axis direction according to their Y coordinate.  
shy - The factor by which coordinates are shifted towards the positive Y axis direction according to their X coordinate.

---

## setTransform

public void **setTransform**(java.awt.geom.AffineTransform Tx)

Sets this transform to a given AffineTransform.

**Throws:**

NullPointerException - if Tx is null

---

## setTransform

public void **setTransform**(PerspectiveTransform Tx)

Sets this transform to a given PerspectiveTransform.

**Throws:**

NullPointerException - if Tx is null

---

## setTransform

public void **setTransform**(float m00,  
float m10,  
float m20,  
float m01,  
float m11,  
float m21,  
float m02,  
float m12,  
float m22)

Sets this transform to a given PerspectiveTransform, expressed by the elements of its matrix.

---

## concatenate

public void **concatenate**(java.awt.geom.AffineTransform Tx)

Post-concatenates a given AffineTransform to this transform.

**Throws:**

NullPointerException - if Tx is null

---

## concatenate

public void **concatenate**(PerspectiveTransform Tx)

Post-concatenates a given PerspectiveTransform to this transform.

**Throws:**

NullPointerException - if Tx is null

---

## preConcatenate

public void **preConcatenate**(java.awt.geom.AffineTransform Tx)

Pre-concatenates a given AffineTransform to this transform.

**Throws:**

NullPointerException - if Tx is null

---

## preConcatenate

public void **preConcatenate**(PerspectiveTransform Tx)

Pre-concatenates a given PerspectiveTransform to this transform.

**Throws:**

NullPointerException - if Tx is null

---

## createInverse

```
public PerspectiveTransform createInverse()  
                                throws java.awt.geom.NoninvertibleTransformException
```

Returns a new PerspectiveTransform that is the inverse of the current transform.

**Throws:**

java.awt.geom.NoninvertibleTransformException - if transform cannot be inverted

---

## createAdjoint

```
public PerspectiveTransform createAdjoint()
```

Returns a new PerspectiveTransform that is the adjoint, of the current transform. The adjoint is defined as the matrix of cofactors, which in turn are the determinants of the submatrices defined by removing the row and column of each element from the original matrix in turn.

The adjoint is a scalar multiple of the inverse matrix. Because points to be transformed are converted into homogeneous coordinates, where scalar factors are irrelevant, the adjoint may be used in place of the true inverse. Since it is unnecessary to normalize the adjoint, it is both faster to compute and more numerically stable than the true inverse.

---

## transform

```
public java.awt.geom.Point2D transform(java.awt.geom.Point2D ptSrc,  
                                       java.awt.geom.Point2D ptDst)
```

Transforms the specified ptSrc and stores the result in ptDst. If ptDst is null, a new Point2D object will be allocated before storing. In either case, ptDst containing the transformed point is returned for convenience. Note that ptSrc and ptDst can be the same. In this case, the input point will be overwritten with the transformed point.

**Parameters:**

ptSrc - The array containing the source point objects.

ptDst - The array where the transform point objects are returned.

**Throws:**

NullPointerException - if ptSrc is null

---

## transform

```
public void transform(java.awt.geom.Point2D[] ptSrc,  
                     int srcOff,  
                     java.awt.geom.Point2D[] ptDst,  
                     int dstOff,  
                     int numPts)
```

Transforms an array of point objects by this transform.

**Parameters:**

ptSrc - The array containing the source point objects.

ptDst - The array where the transform point objects are returned.

srcOff - The offset to the first point object to be transformed in the source array.

dstOff - The offset to the location where the first transformed point object is stored in the destination array.

numPts - The number of point objects to be transformed.

**Throws:**

NullPointerException - if ptSrc is null

ArrayBoundsException - if ptSrc is too small

---

## transform

```
public void transform(float[] srcPts,  
                     int srcOff,  
                     float[] dstPts,  
                     int dstOff,  
                     int numPts)
```

Transforms an array of floating point coordinates by this transform.

**Parameters:**

srcPts - The array containing the source point coordinates. Each point is stored as a pair of x,y coordinates.

srcOff - The offset to the first point to be transformed in the source array.

dstPts - The array where the transformed point coordinates are returned. Each point is stored as a pair of x,y coordinates.

dstOff - The offset to the location where the first transformed point is stored in the destination array.

numPts - The number of points to be transformed.

**Throws:**

NullPointerException - if srcPts is null  
ArrayBoundsException - if srcPts is too small

---

**transform**

```
public void transform(double[] srcPts,  
                     int srcOff,  
                     double[] dstPts,  
                     int dstOff,  
                     int numPts)
```

Transforms an array of double precision coordinates by this transform.

**Parameters:**

srcPts - The array containing the source point coordinates. Each point is stored as a pair of x,y coordinates.  
dstPts - The array where the transformed point coordinates are returned. Each point is stored as a pair of x,y coordinates.  
srcOff - The offset to the first point to be transformed in the source array.  
dstOff - The offset to the location where the first transformed point is stored in the destination array.  
numPts - The number of point objects to be transformed.

**Throws:**

NullPointerException - if srcPts is null  
ArrayBoundsException - if srcPts is too small

---

**transform**

```
public void transform(float[] srcPts,  
                     int srcOff,  
                     double[] dstPts,  
                     int dstOff,  
                     int numPts)
```

Transforms an array of floating point coordinates by this transform, storing the results into an array of doubles.

**Parameters:**

srcPts - The array containing the source point coordinates. Each point is stored as a pair of x,y coordinates.  
srcOff - The offset to the first point to be transformed in the source array.  
dstPts - The array where the transformed point coordinates are returned. Each point is stored as a pair of x,y coordinates.  
dstOff - The offset to the location where the first transformed point is stored in the destination array.  
numPts - The number of points to be transformed.

**Throws:**

NullPointerException - if srcPts is null  
ArrayBoundsException - if srcPts is too small

---

**transform**

```
public void transform(double[] srcPts,  
                     int srcOff,  
                     float[] dstPts,  
                     int dstOff,  
                     int numPts)
```

Transforms an array of double precision coordinates by this transform, storing the results into an array of floats.

**Parameters:**

srcPts - The array containing the source point coordinates. Each point is stored as a pair of x,y coordinates.  
dstPts - The array where the transformed point coordinates are returned. Each point is stored as a pair of x,y coordinates.  
srcOff - The offset to the first point to be transformed in the source array.  
dstOff - The offset to the location where the first transformed point is stored in the destination array.  
numPts - The number of point objects to be transformed.

**Throws:**

NullPointerException - if srcPts is null  
ArrayBoundsException - if srcPts is too small

---

## inverseTransform

```
public java.awt.geom.Point2D inverseTransform(java.awt.geom.Point2D ptSrc,  
                                              java.awt.geom.Point2D ptDst)  
    throws java.awt.geom.NoninvertibleTransformException
```

Inverse transforms the specified ptSrc and stores the result in ptDst. If ptDst is null, a new Point2D object will be allocated before storing. In either case, ptDst containing the transformed point is returned for convenience. Note that ptSrc and ptDst can be the same. In this case, the input point will be overwritten with the transformed point.

### Parameters:

ptSrc - The point to be inverse transformed.  
ptDst - The resulting transformed point.

### Throws:

java.awt.geom.NoninvertibleTransformException - if the matrix cannot be inverted.  
NullPointerException - if ptSrc is null

---

## inverseTransform

```
public void inverseTransform(double[] srcPts,  
                             int srcOff,  
                             double[] dstPts,  
                             int dstOff,  
                             int numPts)  
    throws java.awt.geom.NoninvertibleTransformException
```

Inverse transforms an array of double precision coordinates by this transform.

### Parameters:

srcPts - The array containing the source point coordinates. Each point is stored as a pair of x,y coordinates.  
dstPts - The array where the transformed point coordinates are returned. Each point is stored as a pair of x,y coordinates.  
srcOff - The offset to the first point to be transformed in the source array.  
dstOff - The offset to the location where the first transformed point is stored in the destination array.  
numPts - The number of point objects to be transformed.

### Throws:

java.awt.geom.NoninvertibleTransformException - if the matrix cannot be inverted.  
NullPointerException - if srcPts is null  
ArrayBoundsException - if srcPts is too small  
java.awt.geom.NoninvertibleTransformException - transform cannot be inverted

---

## toString

```
public java.lang.String toString()
```

Returns a String that represents the value of this Object.

### Overrides:

toString in class java.lang.Object

---

## isIdentity

```
public boolean isIdentity()
```

Returns the boolean true value if this PerspectiveTransform is an identity transform. Returns false otherwise.

---

## clone

```
public java.lang.Object clone()
```

Returns a copy of this PerspectiveTransform object.

### Overrides:

clone in class java.lang.Object

---

## equals

```
public boolean equals(java.lang.Object obj)
```

Tests if this PerspectiveTransform equals a supplied one.

### Parameters:

obj - The PerspectiveTransform to be compared to this one.

### Throws:

NullPointerException - if the supplied object is null

**Overrides:**

`equals` in class `java.lang.Object`

---

## javax.media.jai Class PlanarImage

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
```

### Direct Known Subclasses:

OpImage, RemoteImage, RenderedImageAdapter, RenderedOp, Snapshot, SnapshotImage, SnapshotProxy, TiledImage

---

```
public abstract class PlanarImage
extends java.lang.Object
implements ImageJAI, java.awt.image.RenderedImage
```

The fundamental base class representing two-dimensional images.

The `PlanarImage` class provides a home for the functionality common to the JAI classes that implement the `RenderedImage` interface, including `TiledImage` and `OpImage`. These subclasses manipulate the instance variables they inherit from `PlanarImage`, such as the image size, origin, tile dimensions, and tile grid offsets, as well as lists containing the sources and sinks of the image. With these instance variables properly defined, most of the method calls mandated by `RenderedImage` are correctly (if not necessarily optimally) implemented at this level.

Subclasses are responsible for initializing all of the protected instance variables prior to allowing any calls to non-static methods. `PlanarImage` does not perform sanity checking on the state of its instance variables.

`PlanarImage` implements a `createSnapshot` method that produces a new, immutable image with a copy of the source image's current contents. In practice, this snapshot is only a virtual copy; it is managed by the `SnapshotImage` class in such a way as to minimize copying and memory footprint generally. Multiple calls to `createSnapshot` make use of a single `SnapshotImage` per `PlanarImage` in order to centralize version management. These mechanisms are transparent to the API user and are discussed here only for edification.

All non-JAI `RenderedImage` instances must be converted into `PlanarImages` by means of the `RenderedImageAdapter` and `WritableRenderedImageAdapter` classes. The `wrapRenderedImage` method provides a convenient interface to both add a wrapper and take a snapshot if the image is writable. The standard `PlanarImage` constructor used by `OpImages` performs this wrapping automatically. Images that already extend `PlanarImage` will be returned unchanged by `wrapRenderedImage`, that is, it is idempotent.

Going in the other direction, existing code that makes use of the `RenderedImage` interface will be able to use `PlanarImages` directly, without any changes or recompilation. Therefore within JAI images are returned from methods as `PlanarImages`, even though incoming `RenderedImages` are accepted as arguments directly.

The source and sink lists have the effect of creating a graph structure between a set of `PlanarImages`. Note that the practice of making such bidirectional connections between images means that the garbage collector will not inform us when all user references to a node are lost, since there will still be internal references up until the point where the entire graph is detached from user space. A solution is available in the form of *Reference Objects*; see <http://java.sun.com/products/jdk/1.2/docs/guide/refobs/> for more information. These classes include *weak references* that allow the GC to collect objects they reference, setting the reference to null in the process.

The reference problem requires us to be careful about how we define the *reachability* of DAG nodes. If we were to allow nodes to be reached by arbitrary graph traversal, we would be unable to garbage collect any subgraphs of an active graph at all since any node may be reached from any other. Instead, we define the set of reachable nodes as those that may be accessed directly from a reference in user code, or that are the source (not sink) of a reachable node. Reachable nodes are always accessible, whether they are reached by traversing upwards or downwards in the DAG.

A DAG may also contain nodes that are not reachable, that is, they require a downward traversal at some point. Say a node A is reachable, and a call to `A.getSinks()` yields a `Vector` containing a reference to a previously unreachable node B. The node B naturally becomes reachable by virtue of the new user reference pointing to it. However, if the user were to relinquish that reference, the node might be garbage collected, and a future call to `A.getSinks()` might no longer include B in its return value.

Because the set of sinks of a node is inherently unstable, only the `getSinks` method is provided for external access to the sink vector at a node. A hypothetical method such as `getSink` or `getNumSinks` would produce confusing results should a sink be garbage collected between that call and a subsequent call to `getSinks`.

The dimensions and tile grid layout of an image may be completely specified by the instance variables `minX`, `minY`, `width`, `height`, `tileWidth`, `tileHeight`, `tileGridXOffset`, and `tileGridYOffset`. The accessor methods returning these values simply return the values of the corresponding instance variable. All other accessor methods derive their values from these "primitive" accessor methods. This implies that a subclass may set its instance variables at construction time and implement none of the accessor methods, or else may provide implementations of the primitive accessors and simply inherit the others.

### See Also:

---

## Field Detail

---

### **minX**

protected int **minX**

The X coordinate of the image's upper-left pixel.

---

### **minY**

protected int **minY**

The Y coordinate of the image's upper-left pixel.

---

### **width**

protected int **width**

The image's width in pixels.

---

### **height**

protected int **height**

The image's height in pixels.

---

### **tileWidth**

protected int **tileWidth**

The width of a tile.

---

### **tileHeight**

protected int **tileHeight**

The height of a tile.

---

### **tileGridXOffset**

protected int **tileGridXOffset**

The X coordinate of the upper-left pixel of tile (0, 0).

---

### **tileGridYOffset**

protected int **tileGridYOffset**

The Y coordinate of the upper-left pixel of tile (0, 0).

---

### **sampleModel**

protected java.awt.image.SampleModel **sampleModel**

The image's SampleModel.

---

### **colorModel**

protected java.awt.image.ColorModel **colorModel**

The image's ColorModel.

---

## snapshot

protected SnapshotImage **snapshot**

A SnapshotImage that will centralize tile versioning for this image.

---

## properties

private java.util.Hashtable **properties**

A Hashtable containing the image properties.

---

## MIN\_ARRAYCOPY\_SIZE

private static final int **MIN\_ARRAYCOPY\_SIZE**

---

## weakThis

private java.lang.ref.WeakReference **weakThis**

A WeakReference to this image.

---

## sinks

private java.util.AbstractList **sinks**

A set of WeakReferences to the image's sinks.

---

## defaultColorModels

private static final java.awt.image.ColorModel[][] **defaultColorModels**

---

## source0

protected PlanarImage **source0**

The image's first source, stored separately for convenience. `source0` will be `null` for images that have no sources.

---

## source1

protected PlanarImage **source1**

The image's second source, stored separately for convenience. `source0` will be `null` for images that have no or one source.

---

## sources

protected java.util.Vector **sources**

The image's third and later sources, stored in a Vector.

---

## disposed

private boolean **disposed**

## Constructor Detail

### PlanarImage

public **PlanarImage**()

The default constructor.

## Method Detail

## setImageParameters

```
protected void setImageParameters(ImageLayout layout,  
                                   java.awt.image.RenderedImage im)
```

Sets the image bounds, tile grid layout, SampleModel and ColorModel to match those of another image, overriding the image's values with values from an ImageLayout object. This method should only be called during the image construction process.

The image min coordinates, width, height, tile grid offsets, tile width, tile height, SampleModel, and ColorModel are taken either from the image or from the layout.

**Parameters:**

layout - an ImageLayout that is used to selectively override the image's layout, SampleModel, and ColorModel. If null, all parameters will be taken from the image argument.

im - a RenderedImage used as the basis for the layout.

**Throws:**

java.lang.IllegalArgumentException - if im is null.

---

## setImageParameters

```
protected void setImageParameters(java.awt.image.RenderedImage im)
```

Sets the image bounds, tile grid layout, SampleModel and ColorModel to match those of another image. This method should only be called during the image construction process.

**Parameters:**

im - a RenderedImage used as the basis for the layout.

**Throws:**

java.lang.IllegalArgumentException - if im is null.

---

## wrapRenderedImage

```
public static PlanarImage wrapRenderedImage(java.awt.image.RenderedImage im)
```

Wraps an arbitrary RenderedImage to produce a PlanarImage. PlanarImage adds various properties to an image, such as source and sink vectors and the ability to produce snapshots, that are necessary for JAI.

If the image is already a PlanarImage, it is simply returned unchanged. Otherwise, the image is wrapped in a RenderedImageAdapter or WritableRenderedImageAdapter as appropriate.

**Parameters:**

im - a RenderedImage to be used as a source.

**Returns:**

a PlanarImage containing the source's pixel data.

**Throws:**

java.lang.IllegalArgumentException - if im is null.

---

## createSnapshot

```
public PlanarImage createSnapshot()
```

Creates a snapshot, that is, a virtual copy of the image's current contents. If the image is not a WritableRenderedImage, it is returned unchanged. Otherwise, a SnapshotImage is created and the result of calling its createSnapshot() is returned.

**Returns:**

a PlanarImage with immutable contents.

---

## getMinX

```
public int getMinX()
```

Returns the X coordinate of the leftmost column of the image.

**Specified by:**

getMinX in interface java.awt.image.RenderedImage

---

## getMaxX

```
public int getMaxX()
```

Returns the X coordinate of the column immediately to the right of the rightmost column of the image. getMaxX is implemented directly in terms of the instance variables minX and width; therefore subclasses that override getMinX() or getWidth() must also override this method.

---

## **getMinY**

public int **getMinY**()

Returns the Y coordinate of the uppermost row of the image.

**Specified by:**

getMinY in interface java.awt.image.RenderedImage

---

## **getMaxY**

public int **getMaxY**()

Returns the Y coordinate of the row immediately below the bottom row of the image. getMaxY is implemented directly in terms of the instance variables minY and height; therefore subclasses that override getMinY() or getHeight() must also override this method.

---

## **getWidth**

public int **getWidth**()

Returns the width of the image.

**Specified by:**

getWidth in interface java.awt.image.RenderedImage

---

## **getHeight**

public int **getHeight**()

Returns the height of the image.

**Specified by:**

getHeight in interface java.awt.image.RenderedImage

---

## **getTileWidth**

public int **getTileWidth**()

Returns the width of a tile.

**Specified by:**

getTileWidth in interface java.awt.image.RenderedImage

---

## **getTileHeight**

public int **getTileHeight**()

Returns the height of a tile.

**Specified by:**

getTileHeight in interface java.awt.image.RenderedImage

---

## **getTileGridXOffset**

public int **getTileGridXOffset**()

Returns the X coordinate of the upper-left pixel of tile (0, 0).

**Specified by:**

getTileGridXOffset in interface java.awt.image.RenderedImage

---

## **getTileGridYOffset**

public int **getTileGridYOffset**()

Returns the Y coordinate of the upper-left pixel of tile (0, 0).

**Specified by:**

getTileGridYOffset in interface java.awt.image.RenderedImage

---

## **getMinTileX**

public int **getMinTileX**()

Returns the horizontal index of the leftmost column of tiles. `getMinTileX` is implemented as `XToTileX(getMinX())` and so does not need to be implemented by subclasses.

**Specified by:**

`getMinTileX` in interface `java.awt.image.RenderedImage`

---

## **getMaxTileX**

public int **getMaxTileX**()

Returns the horizontal index of the rightmost column of tiles. `getMaxTileX` is implemented as `XToTileX(getMaxX() - 1)` and so does not need to be implemented by subclasses.

---

## **getNumXTiles**

public int **getNumXTiles**()

Returns the number of tiles along the tile grid in the horizontal direction. `getNumXTiles` is implemented as `getMaxTileX() - getMinTileX() + 1` and so does not need to be implemented by subclasses.

**Specified by:**

`getNumXTiles` in interface `java.awt.image.RenderedImage`

---

## **getMinTileY**

public int **getMinTileY**()

Returns the vertical index of the uppermost row of tiles. `getMinTileY` is implemented as `YToTileY(getMinY())` and so does not need to be implemented by subclasses.

**Specified by:**

`getMinTileY` in interface `java.awt.image.RenderedImage`

---

## **getMaxTileY**

public int **getMaxTileY**()

Returns the vertical index of the bottom row of tiles. `getMaxTileY` is implemented as `YToTileY(getMaxY() - 1)` and so does not need to be implemented by subclasses.

---

## **getNumYTiles**

public int **getNumYTiles**()

Returns the number of tiles along the tile grid in the vertical direction. `getNumYTiles` is implemented as `getMaxTileY() - getMinTileY() + 1` and so does not need to be implemented by subclasses.

**Specified by:**

`getNumYTiles` in interface `java.awt.image.RenderedImage`

---

## **getSampleModel**

public `java.awt.image.SampleModel` **getSampleModel**()

Returns the `SampleModel` of the image.

**Specified by:**

`getSampleModel` in interface `java.awt.image.RenderedImage`

---

## **getColorModel**

public `java.awt.image.ColorModel` **getColorModel**()

Returns the `ColorModel` of the image.

**Specified by:**

`getColorModel` in interface `java.awt.image.RenderedImage`

---

```
static void ()
```

---

## createColorModel

```
public static java.awt.image.ColorModel createColorModel(java.awt.image.SampleModel sm)
```

Creates a ColorModel that may be used with the specified SampleModel. If the specified SampleModel is null, this method will throw an IllegalArgumentException. If a suitable ColorModel cannot be found, this method will return null.

Suitable ColorModels are guaranteed to exist for all instances of ComponentSampleModel with no more than 4 bands.

Additionally, a DirectColorModel instance will be created for instances of SinglePixelPackedSampleModel with no more than 4 bands.

For 1- and 3- banded SampleModels, the returned ColorModel will be opaque. For 2- and 4-banded SampleModels, the output will use alpha transparency.

This method is called from the OpImage constructor to supply a ColorModel for images where none has been specified via the ImageLayout parameter.

This method is intended as a useful utility for the creation of simple ColorModels for some common cases. In more complex situations, it may be necessary to instantiate appropriate ColorModels directly.

**Returns:**

an instance of ColorModel, or null.

**Throws:**

java.lang.IllegalArgumentException - if sm is null.

---

## getBounds

```
public java.awt.Rectangle getBounds()
```

Returns a Rectangle indicating the image bounds.

---

## getSource

```
public PlanarImage getSource(int index)
```

Returns an entry from the list of sources. If there is no source corresponding to the specified index, this method will throw an ArrayIndexOutOfBoundsException.

**Parameters:**

index - The index of the desired source.

**Returns:**

A PlanarImage source.

**Throws:**

ArrayIndexOutOfBoundsException - if the index is negative or greater than the maximum source index.

---

## setSource

```
void setSource(PlanarImage source,  
               int index)
```

Helper for RenderedOp.setSource().

---

## addSource

```
protected void addSource(PlanarImage source)
```

Adds a PlanarImage source to the list of sources.

**Parameters:**

source - A PlanarImage to be added as a source.

**Throws:**

java.lang.IllegalArgumentException - if source is null.

---

## addSink

```
protected void addSink(PlanarImage sink)
```

Adds a PlanarImage sink to the list of sinks.

**Parameters:**

sink - A PlanarImage to be added as a sink.

**Throws:**  
java.lang.IllegalArgumentException - if sink is null.

---

## removeSource

protected boolean **removeSource**(PlanarImage source)  
Removes a PlanarImage source from the list of sources.  
**Parameters:**  
source - A PlanarImage to be removed.  
**Returns:**  
true if the element was present, false otherwise.  
**Throws:**  
java.lang.IllegalArgumentException - if source is null.

---

## removeSink

protected boolean **removeSink**(PlanarImage sink)  
Removes a PlanarImage sink from the list of sinks.  
**Parameters:**  
sink - a PlanarImage to be removed.  
**Returns:**  
true if the element was present, false otherwise.  
**Throws:**  
java.lang.IllegalArgumentException - if sink is null.

---

## getSources

public java.util.Vector **getSources**()  
Returns this image's source(s) in a Vector.  
**Specified by:**  
getSources in interface java.awt.image.RenderedImage

---

## getNumSources

public int **getNumSources**()  
Returns the number of PlanarImage sources.

---

## getSinks

public java.util.Vector **getSinks**()  
Returns a Vector containing the currently available PlanarImage sinks of this image (images for which this image is a source), or null if no sinks are present.  
Sinks are stored using weak references. This means that the set of sinks may change between calls to getSinks() if the garbage collector happens to identify a sink as not otherwise reachable (reachability is discussed in the class comments for this class).  
Since the pool of sinks may change as garbage collection occurs, PlanarImage does not implement either a getSink(int index) or a getNumSinks() method. Instead, the caller must call getSinks(), which returns a Vector of normal references. As long as the returned Vector is referenced from user code, the images it references are reachable and may be reliably accessed.

---

## setSources

protected void **setSources**(java.util.List sourceList)  
Set the list of sources from a given List of PlanarImages.  
**Parameters:**  
sourceList - a List of PlanarImages.

---

## removeSources

protected void **removeSources**()  
Clears the list of sources.

---

## removeSinks

protected void **removeSinks**()  
Clears the list of sinks.

---

## getProperties

protected java.util.Hashtable **getProperties**()  
Returns the internal Hashtable containing the image properties.

---

## setProperties

protected void **setProperties**(java.util.Hashtable properties)  
Sets the Hashtable containing the image properties to a given Hashtable. The Hashtable is incorporated by reference and must not be altered by other classes after this method is called.

---

## getProperty

public java.lang.Object **getProperty**(java.lang.String name)  
Gets a property from the property set of this image. If the property name is not recognized, `java.awt.Image.UndefinedProperty` will be returned.  
**Specified by:**  
    **getProperty** in interface `java.awt.image.RenderedImage`  
**Parameters:**  
    name - the name of the property to get, as a String.  
**Returns:**  
    a reference to the property Object, or the value `java.awt.Image.UndefinedProperty`.

---

## setProperty

public void **setProperty**(java.lang.String name,  
                          java.lang.Object value)  
Sets a property on a PlanarImage. Some PlanarImage subclasses may ignore attempts to set properties.  
**Parameters:**  
    name - a String containing the property's name.  
    value - the property, as a general Object.  
**Throws:**  
    java.lang.IllegalArgumentException - if name or value is null.

---

## getPropertyNames

public java.lang.String[] **getPropertyNames**()  
Returns a list of property names that are recognized by this image or null if none are recognized.  
**Specified by:**  
    **getPropertyNames** in interface `java.awt.image.RenderedImage`  
**Returns:**  
    an array of Strings containing valid property names.

---

## getPropertyNames

static java.lang.String[] **getPropertyNames**(java.lang.String[] propertyNames,  
  java.lang.String prefix)  
Utility method to search the full list of property names for matches.

---

## getPropertyNames

```
public java.lang.String[] getPropertyNames(java.lang.String prefix)
```

Returns an array of Strings recognized as names by this property source that begin with the supplied prefix. If no property names match, null will be returned. The comparison is done in a case-independent manner.

The default implementation calls `getPropertyNames()` and searches the list of names for matches.

**Returns:**

an array of Strings giving the valid property names.

**Throws:**

`java.lang.IllegalArgumentException` - if prefix is null.

---

## XToTileX

```
public static int XToTileX(int x,  
                           int tileGridXOffset,  
                           int tileWidth)
```

Converts a pixel's X coordinate into a horizontal tile index relative to a given tile grid layout specified by its X offset and tile width.

If `tileWidth < 0`, the results of this method are undefined. If `tileWidth == 0`, an `ArithmeticException` will be thrown.

**Throws:**

`ArithmeticException` - if `tileWidth == 0`.

---

## YToTileY

```
public static int YToTileY(int y,  
                           int tileGridYOffset,  
                           int tileHeight)
```

Converts a pixel's Y coordinate into a vertical tile index relative to a given tile grid layout specified by its Y offset and tile height.

If `tileHeight < 0`, the results of this method are undefined. If `tileHeight == 0`, an `ArithmeticException` will be thrown.

**Throws:**

`ArithmeticException` - if `tileHeight == 0`.

---

## XToTileX

```
public int XToTileX(int x)
```

Converts a pixel's X coordinate into a horizontal tile index. No attempt is made to detect out-of-range coordinates.

**Parameters:**

x - the X coordinate of a pixel.

**Returns:**

the X index of the tile containing the pixel.

---

## YToTileY

```
public int YToTileY(int y)
```

Converts a pixel's Y coordinate into a vertical tile index. No attempt is made to detect out-of-range coordinates.

**Parameters:**

y - the Y coordinate of a pixel.

**Returns:**

the Y index of the tile containing the pixel.

---

## tileXToX

```
public static int tileXToX(int tx,  
                           int tileGridXOffset,  
                           int tileWidth)
```

Converts a horizontal tile index into the X coordinate of its upper left pixel relative to a given tile grid layout specified by its X offset and tile width.

---

## tileYToY

```
public static int tileYToY(int ty,
                           int tileGridYOffset,
                           int tileHeight)
```

Converts a vertical tile index into the Y coordinate of its upper left pixel relative to a given tile grid layout specified by its Y offset and tile height.

---

## tileXToX

```
public int tileXToX(int tx)
```

Converts a horizontal tile index into the X coordinate of its upper left pixel. No attempt is made to detect out-of-range indices.

**Parameters:**

tx - the horizontal index of a tile.

**Returns:**

the X coordinate of the tile's upper left pixel.

---

## tileYToY

```
public int tileYToY(int ty)
```

Converts a vertical tile index into the Y coordinate of its upper left pixel. No attempt is made to detect out-of-range indices.

**Parameters:**

ty - the vertical index of a tile.

**Returns:**

the Y coordinate of the tile's upper left pixel.

---

## getTileRect

```
public java.awt.Rectangle getTileRect(int tileX,
                                       int tileY)
```

Returns a `Rectangle` indicating the active area of a given tile. The `Rectangle` is defined as the intersection of the tile area and the image bounds. No attempt is made to detect out-of-range indices; tile indices lying completely outside of the image will thus return results with a width and height of 0.

**Parameters:**

tileX - the X index of the tile.

tileY - the Y index of the tile.

**Returns:**

a `Rectangle`

---

## getSplits

```
public void getSplits(IntegerSequence xSplits,
                     IntegerSequence ySplits,
                     java.awt.Rectangle rect)
```

Within a given rectangle, store the list of tile seams of both X and Y directions into the corresponding split sequence.

**Parameters:**

xSplits - An `IntegerSequence` to which the tile seams in the X direction are to be added.

ySplits - An `IntegerSequence` to which the tile seams in the Y direction are to be added.

rect - The rectangular region of interest.

**Throws:**

`java.lang.IllegalArgumentException` - if xSplits is null.

`java.lang.IllegalArgumentException` - if ySplits is null.

`java.lang.IllegalArgumentException` - if rect is null.

---

## getData

```
public java.awt.image.Raster getData()
```

Returns the entire image in a single `Raster`. For images with multiple tiles this will require creating a new `Raster` and copying data from multiple tiles into it ("cobbling").

The returned `Raster` is semantically a copy. This means that subsequent updates to this image will not be reflected in the returned `Raster`. For non-writable (immutable) images, the returned value may be a reference to the image's internal data. The returned `Raster` should be considered non-writable; any attempt to alter its pixel data (such as by casting it to a `WritableRaster` or obtaining and modifying its `DataBuffer`) may result in undefined behavior. The `copyData` method should be used if the returned `Raster` is to be modified.

For a very large image, more than `Integer.MAX_VALUE` entries would be required in the returned `Raster`'s underlying data array. Since the Java language does not permit such an array, an `IllegalArgumentException` will be thrown.

**Specified by:**

`getData` in interface `java.awt.image.RenderedImage`

**Returns:**

A `Raster` containing the entire image data.

**Throws:**

`java.lang.IllegalArgumentException` - if the size of the returned data is too large to be stored in a single `Raster`.

---

## getData

```
public java.awt.image.Raster getData(java.awt.Rectangle region)
```

Returns a specified region of this image in a `Raster`.

The returned `Raster` is semantically a copy. This means that subsequent updates to this image will not be reflected in the returned `Raster`. For non-writable (immutable) images, the returned value may be a reference to the image's internal data. The returned `Raster` should be considered non-writable; any attempt to alter its pixel data (such as by casting it to a `WritableRaster` or obtaining and modifying its `DataBuffer`) may result in undefined behavior. The `copyData` method should be used if the returned `Raster` is to be modified.

The region of the image to be returned is specified by a `Rectangle`. This region may go beyond this image's boundary. If so, the pixels in the areas outside this image's boundary are left unset. Use `getExtendedData` if a specific extension policy is required.

The `region` parameter may also be `null`, in which case the entire image data is returned in the `Raster`.

If `region` is non-`null` but does not intersect the image bounds at all, an `IllegalArgumentException` will be thrown.

It is possible to request a region of an image that would require more than `Integer.MAX_VALUE` entries in the returned `Raster`'s underlying data array. Since the Java language does not permit such an array, an `IllegalArgumentException` will be thrown.

**Specified by:**

`getData` in interface `java.awt.image.RenderedImage`

**Parameters:**

`region` - The rectangular region of this image to be returned, or `null`.

**Returns:**

A `Raster` containing the specified image data.

**Throws:**

`java.lang.IllegalArgumentException` - if the region does not intersect the image bounds.

`java.lang.IllegalArgumentException` - if the size of the returned data is too large to be stored in a single `Raster`.

---

## copyData

```
public java.awt.image.WritableRaster copyData()
```

Copies the entire image into a single raster.

---

## copyData

```
public java.awt.image.WritableRaster copyData(java.awt.image.WritableRaster raster)
```

Copies an arbitrary rectangular region of this image's pixel data into a caller-supplied `WritableRaster`. The region to be copied is defined as the boundary of the `WritableRaster`, which can be obtained by calling `WritableRaster.getBounds()`.

The supplied `WritableRaster` may have a region that is larger than this image's boundary, in which case only pixels in the part of the region that intersects with this image are copied. The areas outside of this image's boundary are left untouched.

The supplied `WritableRaster` may also be `null`, in which case the entire image is copied into a newly-created `WritableRaster` with a `SampleModel` that is compatible with that of this image.

**Specified by:**

`copyData` in interface `java.awt.image.RenderedImage`

**Parameters:**

`raster` - A `WritableRaster` to hold the copied pixel data of this image.

**Returns:**

A reference to the supplied `WritableRaster`, or to a new `WritableRaster` if the supplied one was `null`.

---

## copyExtendedData

```
public void copyExtendedData(java.awt.image.WritableRaster dest,  
                             BorderExtender extender)
```

Copies an arbitrary rectangular region of the `RenderedImage` into a caller-supplied `WritableRaster`. The portion of the supplied `WritableRaster` that lies outside of the bounds of the image is computed by calling the given `BorderExtender`. The supplied `WritableRaster` must have a `SampleModel` that is compatible with that of the image.

**Parameters:**

dest - a `WritableRaster` to hold the returned portion of the image.  
extender - an instance of `BorderExtender`.

**Throws:**

`java.lang.IllegalArgumentException` - if dest or extender is null.

---

## getExtendedData

```
public java.awt.image.Raster getExtendedData(java.awt.Rectangle region,  
                                              BorderExtender extender)
```

Returns a copy of an arbitrary rectangular region of this image in a `Raster`. The portion of the rectangle of interest outside the bounds of the image will be computed by calling the given `BorderExtender`. If the region falls entirely within the image, extender will not be used in any way. Thus it is possible to use a null value for extender when it is known that no actual extension will be required.

The returned `Raster` should be considered non-writable; any attempt to alter its pixel data (such as by casting it to a `WritableRaster` or obtaining and modifying its `DataBuffer`) may result in undefined behavior. The `copyExtendedData` method should be used if the returned `Raster` is to be modified.

**Parameters:**

region - the region of the image to be returned.  
extender - an instance of `BorderExtender`, used only if the region exceeds the image bounds, or null.

**Returns:**

a `Raster` containing the extended data.

**Throws:**

`NullPointerException` - if the region exceeds the image bounds and extender is null.

---

## getAsBufferedImage

```
public java.awt.image.BufferedImage getAsBufferedImage(java.awt.Rectangle rect,  
                                                         java.awt.image.ColorModel colorModel)
```

Returns a copy of this image as a `BufferedImage`. A subarea of the image may be copied by supplying a `Rectangle` parameter; if it is set to null, the entire image is copied. The supplied `Rectangle` will be clipped to the image bounds. The image's `ColorModel` may be overridden by supplying a non-null second argument. The resulting `ColorModel` must be non-null and appropriate for the image's `SampleModel`.

The resulting `BufferedImage` will contain the full requested area, but will always have its upper-left corner translated (0, 0) as required by the `BufferedImage` interface.

**Parameters:**

rect - the `Rectangle` of the image to be copied, or null to indicate that the entire image is to be copied.  
colorModel - a `ColorModel` used to override this image's `ColorModel`, or null. The caller is responsible for supplying a `ColorModel` that is compatible with the image's `SampleModel`.

**Throws:**

`java.lang.IllegalArgumentException` - if an incompatible `ColorModel` is supplied.

---

## getAsBufferedImage

```
public java.awt.image.BufferedImage getAsBufferedImage()
```

Returns a copy of the entire image as a `BufferedImage`. The image's `ColorModel` must be non-null, and appropriate for the image's `SampleModel`.

**See Also:**

`BufferedImage`

---

## getGraphics

```
public java.awt.Graphics getGraphics()
```

Returns a `Graphics` object that may be used to draw into this image. By default, an `IllegalAccessError` is thrown. Subclasses that support such drawing, such as `TiledImage`, may override this method to return a suitable `Graphics` object.

---

## getTile

```
public abstract java.awt.image.Raster getTile(int tileX,  
                                              int tileY)
```

Returns tile (tileX, tileY). Note that tileX and tileY are indices into the tile array, not pixel locations.

Subclasses must override this method to return a non-null value for all tile indices between `getMinTile{X,Y}` and `getMaxTile{X,Y}`, inclusive. Tile indices outside of this region should result in a return value of null.

**Specified by:**

`getTile` in interface `java.awt.image.RenderedImage`

**Parameters:**

`tileX` - the X index of the requested tile in the tile array.

`tileY` - the Y index of the requested tile in the tile array.

---

## getTiles

```
public java.awt.image.Raster[] getTiles(java.awt.Point[] tileIndices)
```

Returns the Rasters indicated by the `tileIndices` array. This call allows certain `PlanarImage` subclasses such as `OpImage` to take advantage of the knowledge that multiple tiles are requested at once.

**Parameters:**

`tileIndices` - An array of Points representing tile indices.

**Returns:**

An array of Raster containing the tiles corresponding to the given tile indices.

---

## prefetchTiles

```
public void prefetchTiles(java.awt.Point[] tileIndices)
```

Hints that the given tiles might be needed in the near future. Some implementations may spawn a thread or threads to compute the tiles while others may ignore the hint.

**Parameters:**

`tileIndices` - A list of tile indices indicating which tiles to prefetch.

---

## dispose

```
public void dispose()
```

Provides a hint that an image will no longer be accessed from a reference in user space. The results are equivalent to those that occur when the program loses its last reference to this image, the garbage collector discovers this, and `finalize` is called. This can be used as a hint in situations where waiting for garbage collection would be overly conservative.

`PlanarImage` defines this method to remove the image being disposed from the list of sinks in all of its source images.

Subclasses should call `super.dispose()` in their `dispose` methods, if any.

The results of referencing an image after a call to `dispose()` are undefined.

---

## finalize

```
protected void finalize()  
    throws java.lang.Throwable
```

Performs cleanup prior to garbage collection.

**Throws:**

`Throwable` - if an error occurs in the garbage collector.

**Overrides:**

`finalize` in class `java.lang.Object`

---

## printBounds

```
private void printBounds()
```

For debugging.

---

### **print\_tile**

```
private void print_tile(int i,  
                        int j)
```

For debugging.

---

### **print**

```
private void print()
```

For debugging.

---

### **cobbleByte**

```
private void cobbleByte(java.awt.Rectangle bounds,  
                        java.awt.image.Raster dstRaster)
```

---

### **cobbleShort**

```
private void cobbleShort(java.awt.Rectangle bounds,  
                        java.awt.image.Raster dstRaster)
```

---

### **cobbleUShort**

```
private void cobbleUShort(java.awt.Rectangle bounds,  
                        java.awt.image.Raster dstRaster)
```

---

### **cobbleInt**

```
private void cobbleInt(java.awt.Rectangle bounds,  
                        java.awt.image.Raster dstRaster)
```

---

### **cobbleFloat**

```
private void cobbleFloat(java.awt.Rectangle bounds,  
                        java.awt.image.Raster dstRaster)
```

---

### **cobbleDouble**

```
private void cobbleDouble(java.awt.Rectangle bounds,  
                        java.awt.image.Raster dstRaster)
```

---

## javax.media.jai Class PointOpImage

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|   |
|   +-- javax.media.jai.OpImage
|       |
|       +-- javax.media.jai.PointOpImage
```

### Direct Known Subclasses:

NullOpImage

---

public abstract class **PointOpImage**

extends OpImage

An abstract base class for image operators that require only the (x, y) pixel from each source image in order to compute the destination pixel (x, y).

PointOpImage is intended as a convenient superclass for OpImage>s that only need to look at each destination pixel's corresponding source pixels. Some examples are lookup, contrast adjustment, pixel arithmetic, and color space conversion.

**See Also:** <B>

### Constructor Detail

## PointOpImage

```
public PointOpImage(java.util.Vector sources,
                    TileCache cache,
                    ImageLayout layout,
                    boolean cobbleSources)
```

Constructs a PointOpImage with a Vector of RenderedImages as its sources.

The layout parameter is passed to the superclass constructor unchanged, where it is used along with the source image layouts to determine the output image layout in the standard way.

### Parameters:

sources - The source images.

cache - A TileCache object to store tiles from this OpImage, or null. If null, a default cache will be used.

layout - The layout parameters of the destination image.

cobbleSources - true if computeRect() expects contiguous sources.

### Throws:

java.lang.IllegalArgumentException - if combining the intersected source bounds with the layout parameter results in negative output width or height.

---

## PointOpImage

```
public PointOpImage(java.awt.image.RenderedImage source,
                    TileCache cache,
                    ImageLayout layout,
                    boolean cobbleSources)
```

Constructs a PointOpImage with one source image. The image layout is computed as described in the constructor taking a Vector of sources.

### Parameters:

source - The source image.

cache - A TileCache object to store tiles from this OpImage, or null. If null, a default cache will be used.

layout - The layout parameters of the destination image.

cobbleSources - Indicates whether computeRect() expects contiguous sources.

---

## PointOpImage

```
public PointOpImage(java.awt.image.RenderedImage source0,
                    java.awt.image.RenderedImage source1,
                    TileCache cache,
                    ImageLayout layout,
                    boolean cobbleSources)
```

Constructs a PointOpImage with two source images. The image layout is computed as described in the constructor taking a Vector of sources.

### Parameters:

source0 - The first source image.

source1 - The second source image.

cache - A TileCache object to store tiles from this OpImage, or null. If null, a default cache will be used.

layout - The layout parameters of the destination image.

cobbleSources - Indicates whether computeRect() expects contiguous sources.

---

## PointOpImage

```
public PointOpImage(java.awt.image.RenderedImage source0,
                    java.awt.image.RenderedImage source1,
                    java.awt.image.RenderedImage source2,
                    TileCache cache,
                    ImageLayout layout,
                    boolean cobbleSources)
```

Constructs a PointOpImage with three source images. The image layout is computed as described in the constructor taking a Vector of sources.

### Parameters:

source0 - The first source image.

source1 - The second source image.

source2 - The third source image.

cache - A TileCache object to store tiles from this OpImage, or null. If null, a default cache will be used.

layout - The layout parameters of the destination image.

cobbleSources - Indicates whether computeRect() expects contiguous sources.

## Method Detail

### initializeFields

```
private void initializeFields()
```

### hasCompatibleSampleModel

```
private boolean hasCompatibleSampleModel(PlanarImage src)
```

### permitInPlaceOperation

```
protected void permitInPlaceOperation()
```

Causes a flag to be set to indicate that in-place operation should be permitted if the image bounds, tile grid offset, tile dimensions, and SampleModels of the source and destination images are compatible. This method should be invoked in the constructor of the implementation of a given operation only if that implementation is amenable to in-place computation. Invocation of this method is a necessary but not a sufficient condition for in-place computation actually to occur. If the system property "javax.media.jai.PointOpImage.InPlace" is equal to the string "false" in a case-insensitive fashion then in-place operation will not be permitted.

### computeTile

```
public java.awt.image.Raster computeTile(int tileX,  
                                         int tileY)
```

Computes a tile. If source cobbling was requested at construction time, the source tile boundaries are overlayed onto the destination and `computeRect(Raster[], WritableRaster, Rectangle)` is called for each of the resulting regions. Otherwise, `computeRect(PlanarImage[], WritableRaster, Rectangle)` is called once to compute the entire active area of the tile.

The image bounds may be larger than the bounds of the source image. In this case, samples for which there are no no corresponding sources are set to zero.

**Parameters:**

tileX - The X index of the tile.  
tileY - The Y index of the tile.

**Overrides:**

computeTile in class OpImage

### mapSourceRect

```
public final java.awt.Rectangle mapSourceRect(java.awt.Rectangle sourceRect,  
                                              int sourceIndex)
```

Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**Parameters:**

sourceRect - the Rectangle in source coordinates.  
sourceIndex - the index of the source image.

**Returns:**

a Rectangle indicating the potentially affected destination region, or null if the region is unknown.

**Throws:**

java.lang.IllegalArgumentException - if sourceIndex is negative or greater than the index of the last source.  
NullPointerException - if sourceRect is null.

**Overrides:**

mapSourceRect in class OpImage

### mapDestRect

```
public final java.awt.Rectangle mapDestRect(java.awt.Rectangle destRect,  
                                            int sourceIndex)
```

Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**Parameters:**

destRect - the Rectangle in source coordinates.  
sourceIndex - the index of the source image.

**Returns:**

a `Rectangle` indicating the potentially affected destination region, or `null` if the region is unknown.

**Throws:**

`java.lang.IllegalArgumentException` - if `sourceIndex` is negative or greater than the index of the last source.

`NullPointerException` - if `destRect` is `null`.

**Overrides:**

`mapDestRect` in class `OpImage`

---

## javax.media.jai Class ProductOperationGraph

java.lang.Object  
|-- javax.media.jai.ProductOperationGraph

---

### class ProductOperationGraph

extends java.lang.Object  
implements java.io.Serializable

ProductOperationGraph manages a list of operations (image factories) belonging to a particular product. The operations have pairwise preferences between them. The `getOrderedOperationList` method performs a topological sort. The topological sort follows the algorithm described in Horowitz and Sahni, *Fundamentals of Data Structures* (1976), p. 315.

Several minor changes are made to their implementation. First, nodes are represented as objects, not as integers. The count (in-degree) field is not used to link zero in-degree objects, but instead a separate `zeroLink` field is used. The neighbor lists are stored as Vectors, not linked lists, and enumerations are used to iterate over them.

This class is used by the implementation of the `OperationRegistry` class and is not intended to be part of the API.

---

### Field Detail

#### operations

protected java.util.Vector **operations**  
A Vector of RIF implementations.

---

#### orderedProducts

protected java.util.Vector **orderedProducts**  
A cached version of the ordered product list

---

#### isChanged

protected boolean **isChanged**  
Signifies whether the cached copy is out of date.

---

#### lock

com.sun.media.jai.util.ReaderWriterLock **lock**

---

### Constructor Detail

#### ProductOperationGraph

public **ProductOperationGraph**()  
Constructs an ProductOperationGraph.

---

### Method Detail

#### addProduct

public void **addProduct**(java.lang.String productName)  
Adds a product to an ProductOperationGraph. A new PartialOrderNode is constructed to hold the product and its graph adjacency information.

---

## **lookupOp**

public PartialOrderNode **lookupOp**(java.lang.String productName)

Locates a product from within the vector of PartialOrderNodes using the productName provided. NOTE: CHANGING access from private to public

---

## **setPreference**

public void **setPreference**(java.lang.String preferredOp,  
java.lang.String otherOp)

Sets a preference between two products.

---

## **unsetPreference**

public void **unsetPreference**(java.lang.String preferredOp,  
java.lang.String otherOp)

Removes a preference between two products.

---

## **getOrderedOperationList**

public java.util.Vector **getOrderedOperationList**()

Performs a topological sort on the set of RIFs.

---

javax.media.jai

## Interface PropertyGenerator

### All Known Implementing Classes:

PropertyGeneratorFromSource, CopyPropertyGenerator, PolarToComplexPropertyGenerator, ImageFunctionPropertyGenerator, WarpPropertyGenerator, MagnitudePropertyGenerator, PhasePropertyGenerator, MultiplyComplexPropertyGenerator, TransposePropertyGenerator, TranslatePropertyGenerator, DFTPropertyGenerator, ShearPropertyGenerator, AffinePropertyGenerator, RotatePropertyGenerator, IDFTPropertyGenerator, MagnitudeSquaredPropertyGenerator, ConjugatePropertyGenerator, DivideComplexPropertyGenerator, ScalePropertyGenerator

---

public abstract interface **PropertyGenerator**

extends java.io.Serializable

An interface through which properties may be computed dynamically with respect to an environment of pre-existing properties. In the interest of simplicity and consistency, a PropertyGenerator is required to be a pure function; that is, if called multiple times with the same environment it must produce identical results.

The OperationRegistry class allows PropertyGenerators to be associated with a particular operation type, and will automatically insert them into imaging chains as needed.

---

## Method Detail

### getPropertyNames

public java.lang.String[] **getPropertyNames**()

Returns an array of Strings naming properties emitted by this property generator.

**Returns:**

an array of Strings that may be passed as parameter names to the getProperty() method.

---

### getProperty

public java.lang.Object **getProperty**(java.lang.String name,  
RenderedOp op)

Computes the value of a property relative to an environment of pre-existing properties emitted by the sources of a RenderedOp, and the parameters of that operation.

The operation name, sources, and ParameterBlock of the RenderedOp being processed may be obtained by means of the op.getOperationName(), op.getSources(), and op.getParameterBlock() methods. It is legal to call getProperty() on the operation's sources.

**Parameters:**

name - the name of the property, as a String.  
op - the RenderedOp representing the operation.

**Returns:**

the value of the property, as an Object.

---

### getProperty

public java.lang.Object **getProperty**(java.lang.String name,  
RenderableOp op)

Computes the value of a property relative to an environment of pre-existing properties emitted by the sources of a RenderableOp, and the parameters of that operation.

The operation sources and ParameterBlock of the RenderableOp being processed may be obtained by means of the op.getSources() and op.getParameterBlock() methods. It is legal to call getProperty() on the operation's sources.

**Parameters:**

name - the name of the property, as a String.  
op - the RenderableOp representing the operation.

**Returns:**

the value of the property, as an Object.

---

javax.media.jai

## Class PropertyGeneratorFromSource

java.lang.Object

|-- javax.media.jai.PropertyGeneratorFromSource

---

class **PropertyGeneratorFromSource**

extends java.lang.Object

implements PropertyGenerator

A class that implements the PropertyGenerator interface. This class is used when a property is to be calculated from a particular source.

---

### Field Detail

#### sourceIndex

int **sourceIndex**

---

#### propertyName

java.lang.String **propertyName**

---

### Constructor Detail

#### PropertyGeneratorFromSource

```
PropertyGeneratorFromSource(int sourceIndex,  
                             java.lang.String propertyName)
```

---

### Method Detail

#### getPropertyNames

```
public java.lang.String[] getPropertyNames()
```

**Specified by:**

getPropertyNames in interface PropertyGenerator

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,  
                                     RenderedOp op)
```

**Specified by:**

getProperty in interface PropertyGenerator

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,  
                                     RenderableOp op)
```

**Specified by:**

getProperty in interface PropertyGenerator

---

---

## javax.media.jai Interface PropertySource

### All Known Subinterfaces:

ImageJAI

### All Known Implementing Classes:

PropertySourceImpl, RenderableImageAdapter, RenderableOp

---

public abstract interface **PropertySource**

An interface encapsulating the set of operations involved in identifying and reading properties.

The interface consists of the `getProperty()` and `getPropertyNames()` methods familiar from the `RenderedImage` and `RenderableImage` interfaces.

`PropertySource` is implemented by `PlanarImage`. Since all `RenderedImages` used with JAI are "wrapped" by a `RenderedImageAdapter`, all JAI images may be assumed to implement `PropertySource`.

### See Also:

`RenderedImage`, `RenderableImage`

---

## Method Detail

### getPropertyNames

```
public java.lang.String[] getPropertyNames()
```

Returns an array of `Strings` recognized as names by this property source. If no properties are available, `null` will be returned.

#### Returns:

an array of `Strings` giving the valid property names.

---

### getPropertyNames

```
public java.lang.String[] getPropertyNames(java.lang.String prefix)
```

Returns an array of `Strings` recognized as names by this property source that begin with the supplied prefix. If no property names match, `null` will be returned. The comparison is done in a case-independent manner.

#### Returns:

an array of `Strings` giving the valid property names.

---

### getProperty

```
public java.lang.Object getProperty(java.lang.String name)
```

Returns the value of a property. If the property name is not recognized, `java.awt.Image.UndefinedProperty` will be returned.

#### Parameters:

`name` - the name of the property, as a `String`.

#### Returns:

the value of the property, as an `Object`, or the value `java.awt.Image.UndefinedProperty`.

---

## javax.media.jai Class PropertySourceImpl

java.lang.Object  
|  
+-- javax.media.jai.PropertySourceImpl

---

class **PropertySourceImpl**  
extends java.lang.Object  
implements PropertySource  
A class that implements the PropertySource interface.

---

### Field Detail

#### pg

java.util.Vector **pg**

---

#### sources

java.util.Vector **sources**

---

#### suppNames

java.util.Vector **suppNames**

---

#### sourceForProp

java.util.Hashtable **sourceForProp**

---

#### isRendered

boolean **isRendered**

---

#### op

java.lang.Object **op**

---

#### propNames

private java.util.Hashtable **propNames**

---

### Constructor Detail

#### PropertySourceImpl

```
public PropertySourceImpl(java.util.Vector sources,  
                           java.util.Vector generators,  
                           java.util.Vector suppressed,  
                           java.util.Hashtable sourceForProp,  
                           RenderedOp op)
```

---

#### PropertySourceImpl

```
public PropertySourceImpl(java.util.Vector sources,  
                           java.util.Vector generators,  
                           java.util.Vector suppressed,  
                           java.util.Hashtable sourceForProp,  
                           RenderableOp op)
```

## Method Detail

### getPropertyNames

```
public java.lang.String[] getPropertyNames()
```

Returns an array of Strings recognized as names by this property source.

**Specified by:**

getPropertyNames in interface PropertySource

**Returns:**

an array of Strings giving the valid property names.

---

### getPropertyNames

```
public java.lang.String[] getPropertyNames(java.lang.String prefix)
```

Returns an array of Strings recognized as names by this property source that begin with the supplied prefix. If no property names match, null will be returned. The comparison is done in a case-independent manner.

The default implementation calls `getPropertyNames()` and searches the list of names for matches.

**Specified by:**

getPropertyNames in interface PropertySource

**Returns:**

an array of Strings giving the valid property names.

---

### getProperty

```
public java.lang.Object getProperty(java.lang.String name)
```

Returns the value of a property.

**Specified by:**

getProperty in interface PropertySource

**Parameters:**

name - the name of the property, as a String.

**Returns:**

the value of the property, as an Object.

---

### copyPropertyFromSource

```
public void copyPropertyFromSource(java.lang.String propertyName,  
                                   int sourceIndex)
```

---

### suppressProperty

```
public void suppressProperty(java.lang.String propertyName)
```

---

### addPropertyGenerator

```
public void addPropertyGenerator(PropertyGenerator generator)
```

---

### removePropertyGenerator

```
public void removePropertyGenerator(PropertyGenerator generator)
```

---

### removeSuppressedProps

```
private void removeSuppressedProps(PropertyGenerator generator)
```

---

### hashNames

```
private void hashNames()
```

---

## javax.media.jai

### Class ROI

java.lang.Object

|-- javax.media.jai.ROI

#### Direct Known Subclasses:

ROIShape

---

public class **ROI**

extends java.lang.Object

implements java.io.Serializable

The parent class for representations of a region of interest of an image. This class represents region information in image form, and can thus be used as a fallback where a Shape representation is unavailable. Where possible, subclasses such as ROIShape are used since they provide a more compact means of storage for large regions.

The getAsShape() method may be called optimistically on any instance of ROI; however, it may return null to indicate that a Shape representation of the ROI is not available. In this case, getAsImage() should be called as a fallback.

Inclusion and exclusion of pixels is defined by a threshold value. Pixel values greater than or equal to the threshold indicate inclusion.

---

### Field Detail

#### iter

private transient RandomIter **iter**

A RandomIter used to grab pixels from the ROI.

---

#### theImage

transient PlanarImage **theImage**

The PlanarImage representation of the ROI.

---

#### threshold

int **threshold**

The inclusion/exclusion threshold of the ROI.

---

### Constructor Detail

#### ROI

protected **ROI**()

The default constructor.

---

#### ROI

public **ROI**(java.awt.image.RenderedImage im)

Constructs an ROI from a RenderedImage. The inclusion threshold is taken to be halfway between the minimum and maximum sample values specified by the image's SampleModel.

##### Parameters:

im - A single-banded RenderedImage.

##### Throws:

java.lang.IllegalArgumentException - if im is null.

---

## ROI

```
public ROI(java.awt.image.RenderedImage im,  
           int threshold)
```

Constructs an ROI from a RenderedImage. The inclusion threshold is specified explicitly.

**Parameters:**

im - A single-banded RenderedImage.  
threshold - The desired inclusion threshold.

**Throws:**

java.lang.IllegalArgumentException - if im is null.

## Method Detail

### mergeRunLengthList

```
protected static java.util.LinkedList mergeRunLengthList(java.util.LinkedList rectList)
```

Merge a LinkedList of Rectangles representing run lengths of pixels in the ROI into a minimal list wherein vertically abutting Rectangles are merged. The operation is effected in place.

**Parameters:**

rectList - The list of run length Rectangles.

**Returns:**

The merged list.

**Throws:**

NullPointerException - if rectList is null.

### mergeImages

```
private static PlanarImage mergeImages(PlanarImage im1,  
                                       PlanarImage im2,  
                                       PlanarImage overlap)
```

### getIter

```
private RandomIter getIter()
```

Get the iterator, construct it if need be.

### getThreshold

```
public int getThreshold()
```

Returns the inclusion/exclusion threshold value.

### setThreshold

```
public void setThreshold(int threshold)
```

Sets the inclusion/exclusion threshold value.

### getBounds

```
public java.awt.Rectangle getBounds()
```

Returns the bounds of the ROI as a Rectangle.

### getBounds2D

```
public java.awt.geom.Rectangle2D getBounds2D()
```

Returns the bounds of the ROI as a Rectangle2D.

### contains

```
public boolean contains(java.awt.Point p)
```

Returns true if the ROI contains a given Point.

**Parameters:**

p - A Point identifying the pixel to be queried.

**Returns:**  
true if the pixel lies within the ROI.  
**Throws:**  
NullPointerException - if p is null.

---

## contains

public boolean **contains**(java.awt.geom.Point2D p)  
Returns true if the ROI contains a given Point2D.  
**Parameters:**  
p - A Point2D identifying the pixel to be queried.  
**Returns:**  
true if the pixel lies within the ROI.  
**Throws:**  
NullPointerException - if p is null.

---

## contains

public boolean **contains**(int x,  
int y)  
Returns true if the ROI contains the point (x, y).  
**Parameters:**  
x - An int specifying the X coordinate of the pixel to be queried.  
y - An int specifying the Y coordinate of the pixel to be queried.  
**Returns:**  
true if the pixel lies within the ROI.

---

## contains

public boolean **contains**(double x,  
double y)  
Returns true if the ROI contain the point (x, y).  
**Parameters:**  
x - A double specifying the X coordinate of the pixel to be queried.  
y - A double specifying the Y coordinate of the pixel to be queried.  
**Returns:**  
true if the pixel lies within the ROI.

---

## contains

public boolean **contains**(java.awt.Rectangle rect)  
Returns true if a given Rectangle is entirely included within the ROI.  
**Parameters:**  
rect - A Rectangle specifying the region to be tested for inclusion.  
**Returns:**  
true if the rectangle is entirely contained within the ROI.  
**Throws:**  
NullPointerException - if rect is null.

---

## contains

public boolean **contains**(java.awt.geom.Rectangle2D rect)  
Returns true if a given Rectangle2D is entirely included within the ROI.  
**Parameters:**  
rect - A Rectangle2D specifying the region to be tested for inclusion.  
**Returns:**  
true if the rectangle is entirely contained within the ROI.  
**Throws:**  
NullPointerException - if rect is null.

---

## contains

```
public boolean contains(int x,  
                        int y,  
                        int w,  
                        int h)
```

Returns true if a given rectangle (x, y, w, h) is entirely included within the ROI.

**Parameters:**

x - The int X coordinate of the upper left corner of the region.  
y - The int Y coordinate of the upper left corner of the region.  
w - The int width of the region.  
h - The int height of the region.

**Returns:**

true if the rectangle is entirely contained within the ROI.

---

## contains

```
public boolean contains(double x,  
                        double y,  
                        double w,  
                        double h)
```

Returns true if a given rectangle (x, y, w, h) is entirely included within the ROI.

**Parameters:**

x - The double X coordinate of the upper left corner of the region.  
y - The double Y coordinate of the upper left corner of the region.  
w - The double width of the region.  
h - The double height of the region.

**Returns:**

true if the rectangle is entirely contained within the ROI.

---

## intersects

```
public boolean intersects(java.awt.Rectangle rect)
```

Returns true if a given Rectangle intersects the ROI.

**Parameters:**

rect - A Rectangle specifying the region to be tested for inclusion.

**Returns:**

true if the rectangle intersects the ROI.

**Throws:**

NullPointerException - if rect is null.

---

## intersects

```
public boolean intersects(java.awt.geom.Rectangle2D r)
```

Returns true if a given Rectangle2D intersects the ROI.

**Parameters:**

r - A Rectangle2D specifying the region to be tested for inclusion.

**Returns:**

true if the rectangle intersects the ROI.

**Throws:**

NullPointerException - if r is null.

---

## intersects

```
public boolean intersects(int x,  
                        int y,  
                        int w,  
                        int h)
```

Returns true if a given rectangular region intersects the ROI.

**Parameters:**

x - The int X coordinate of the upper left corner of the region.  
y - The int Y coordinate of the upper left corner of the region.  
w - The int width of the region.  
h - The int height of the region.

**Returns:**  
true if the rectangle intersects the ROI.

---

## intersects

```
public boolean intersects(double x,  
                        double y,  
                        double w,  
                        double h)
```

Returns true if a given rectangular region intersects the ROI.

**Parameters:**  
x - The double X coordinate of the upper left corner of the region.  
y - The double Y coordinate of the upper left corner of the region.  
w - The double width of the region.  
h - The double height of the region.

**Returns:**  
true if the rectangle intersects the ROI.

---

## add

```
public ROI add(ROI roi)
```

Adds another ROI to this one and returns the result as a new ROI. The supplied ROI will be converted to a rendered form if necessary.

**Parameters:**  
roi - An ROI.

**Returns:**  
A new ROI containing the new ROI data.

**Throws:**  
NullPointerException - if roi is null.

---

## subtract

```
public ROI subtract(ROI roi)
```

Subtracts another ROI from this one and returns the result as a new ROI. The supplied ROI will be converted to a rendered form if necessary.

**Parameters:**  
roi - An ROI.

**Returns:**  
A new ROI containing the new ROI data.

**Throws:**  
NullPointerException - if roi is null.

---

## intersect

```
public ROI intersect(ROI roi)
```

Intersects the ROI with another ROI and returns the result as a new ROI. The supplied ROI will be converted to a rendered form if necessary.

**Parameters:**  
roi - An ROI.

**Returns:**  
A new ROI containing the new ROI data.

**Throws:**  
NullPointerException - if roi is null.

---

## exclusiveOr

```
public ROI exclusiveOr(ROI roi)
```

Exclusive-ors the ROI with another ROI and returns the result as a new ROI. The supplied ROI will be converted to a rendered form if necessary.

**Parameters:**  
roi - An ROI.

**Returns:**  
A new ROI containing the new ROI data.

**Throws:**  
NullPointerException - if roi is null.

---

## transform

```
public ROI transform(java.awt.geom.AffineTransform at,  
                    Interpolation interp)
```

Performs an affine transformation and returns the result as a new ROI. The transformation is performed by an "Affine" RIF using the indicated interpolation method.

**Parameters:**  
at - an AffineTransform specifying the transformation.  
interp - the Interpolation to be used.

**Returns:**  
a new ROI containing the transformed ROI data.

**Throws:**  
NullPointerException - if at is null.  
NullPointerException - if interp is null.

---

## transform

```
public ROI transform(java.awt.geom.AffineTransform at)
```

Performs an affine transformation and returns the result as a new ROI. The transformation is performed by an "Affine" RIF using nearest neighbor interpolation.

**Parameters:**  
at - an AffineTransform specifying the transformation.

**Returns:**  
a new ROI containing the transformed ROI data.

**Throws:**  
NullPointerException - if at is null.

---

## performImageOp

```
public ROI performImageOp(java.awt.image.renderable.RenderedImageFactory RIF,  
                           java.awt.image.renderable.ParameterBlock paramBlock,  
                           int sourceIndex,  
                           java.awt.RenderingHints renderHints)
```

Transforms an ROI using an imaging operation. The operation is specified by a RenderedImageFactory. The operation's ParameterBlock, minus the image source itself is supplied, along with an index indicating where to insert the ROI image. The renderHints argument allows rendering hints to be passed in.

**Parameters:**  
RIF - A RenderedImageFactory that will be used to create the op.  
paramBlock - A ParameterBlock containing all sources and parameters for the op except for the ROI itself.  
sourceIndex - The index of the ParameterBlock's sources where the ROI is to be inserted.  
renderHints - A RenderingHints object containing rendering hints, or null.

**Throws:**  
NullPointerException - if RIF is null.  
NullPointerException - if paramBlock is null.

---

## performImageOp

```
public ROI performImageOp(java.lang.String name,  
                           java.awt.image.renderable.ParameterBlock paramBlock,  
                           int sourceIndex,  
                           java.awt.RenderingHints renderHints)
```

Transforms an ROI using an imaging operation. The operation is specified by name; the default JAI registry is used to resolve this into a RIF. The operation's ParameterBlock, minus the image source itself is supplied, along with an index indicating where to insert the ROI image. The renderHints argument allows rendering hints to be passed in.

**Parameters:**  
name - The name of the operation to perform.  
paramBlock - A ParameterBlock containing all sources and parameters for the op except for the ROI itself.  
sourceIndex - The index of the ParameterBlock's sources where the ROI is to be inserted.  
renderHints - A RenderingHints object containing rendering hints, or null.

**Throws:**  
NullPointerException - if name is null.  
NullPointerException - if paramBlock is null.

---

## getAsShape

```
public java.awt.Shape getAsShape()
```

Returns a Shape representation of the ROI, if possible. If none is available, null is returned. A proper instance of ROI (one that is not an instance of any subclass of ROI) will always return null.

**Returns:**

The ROI as a Shape.

---

## getAsImage

```
public PlanarImage getAsImage()
```

Returns a PlanarImage representation of the ROI. This method will always succeed.

**Returns:**

The ROI as a PlanarImage.

---

## getAsBitmask

```
public int[][] getAsBitmask(int x,  
                             int y,  
                             int width,  
                             int height,  
                             int[][] mask)
```

Returns a bitmask for a given rectangular region of the ROI indicating whether the pixel is included in the region of interest. The results are packed into 32-bit integers, with the MSB considered to lie on the left. The last entry in each row of the result may have bits that lie outside of the requested rectangle. These bits are guaranteed to be zeroed.

The mask array, if supplied, must be of length equal to or greater than height and each of its subarrays must have length equal to or greater than (width + 31)/32. If null is passed in, a suitable array will be constructed. If the mask is non-null but has insufficient size, an exception will be thrown.

**Parameters:**

x - The X coordinate of the upper left corner of the rectangle.

y - The Y coordinate of the upper left corner of the rectangle.

width - The width of the rectangle.

height - The height of the rectangle.

mask - A two-dimensional array of ints at least (width + 31)/32 entries wide and (height) entries tall, or null.

**Returns:**

A reference to the mask parameter, or to a newly constructed array if mask is null.

---

## getAsRectangleList

```
public java.util.LinkedList getAsRectangleList(int x,  
                                                  int y,  
                                                  int width,  
                                                  int height)
```

Returns a LinkedList of Rectangles for a given rectangular region of the ROI. The Rectangles in the list are merged into a minimal set.

**Parameters:**

x - The X coordinate of the upper left corner of the rectangle.

y - The Y coordinate of the upper left corner of the rectangle.

width - The width of the rectangle.

height - The height of the rectangle.

**Returns:**

A LinkedList of Rectangles.

---

## getAsRectangleList

```
protected java.util.LinkedList getAsRectangleList(int x,  
                                                    int y,  
                                                    int width,  
                                                    int height,  
                                                    boolean mergeRectangles)
```

Returns a LinkedList of Rectangles for a given rectangular region of the ROI.

**Parameters:**

x - The X coordinate of the upper left corner of the rectangle.

y - The Y coordinate of the upper left corner of the rectangle.

width - The width of the rectangle.

height - The height of the rectangle.  
mergeRectangles - true if the Rectangles are to be merged into a minimal set.

**Returns:**

A LinkedList of Rectangles.

---

## **writeObject**

```
private void writeObject(java.io.ObjectOutputStream out)
    throws java.io.IOException
```

Serialize the ROI.

**Parameters:**

out - The ObjectOutputStream.

---

## **readObject**

```
private void readObject(java.io.ObjectInputStream in)
    throws java.io.IOException,
           java.lang.ClassNotFoundException
```

Deserialize the ROI.

**Parameters:**

in - The ObjectInputStream.

---

**javax.media.jai**

## **Class ROIShape.PolyShape.PolyEdge**

java.lang.Object

|-- **javax.media.jai.ROIShape.PolyShape.PolyEdge**

---

private class **ROIShape.PolyShape.PolyEdge**

extends java.lang.Object

implements java.util.Comparator

Inner class representing a polygon edge.

---

### **Field Detail**

#### **x**

public double **x**

X coordinate of intersection of edge with current scanline.

---

#### **dx**

public double **dx**

Change in X with respect to Y.

---

#### **i**

public int **i**

The edge number: edge i goes from vertex i to vertex i+1.

---

### **Constructor Detail**

#### **ROIShape.PolyShape.PolyEdge**

**ROIShape.PolyShape.PolyEdge**(double x,  
double dx,  
int i)

Construct a PolyEdge object.

##### **Parameters:**

x - X coordinate of edge intersection with scanline.

dx - The change in X with respect to Y.

i - The edge number.

---

### **Method Detail**

#### **compare**

public int **compare**(java.lang.Object o1,  
java.lang.Object o2)

Implementation of java.util.Comparator.compare. The argument Objects are assumed to be PolyEdges and are sorted on the basis of their respective x components.

##### **Specified by:**

compare in interface java.util.Comparator

##### **Parameters:**

o1 - The first PolyEdge object.

o2 - The second PolyEdge object.

##### **Returns:**

-1 if o1 < o2, 1 if o1 > o2, 0 if o1 == o2.

---

---

## javax.media.jai Class ROIShape.PolyShape

java.lang.Object  
|  
+-- javax.media.jai.ROIShape.PolyShape

---

private class **ROIShape.PolyShape**  
extends java.lang.Object  
Instance inner class used for scan conversion of a polygonal Shape.

---

### Field Detail

#### POLYGON\_UNCLASSIFIED

private static final int **POLYGON\_UNCLASSIFIED**  
A polygon which has yet to be classified as one of the following types.

---

#### POLYGON\_DEGENERATE

private static final int **POLYGON\_DEGENERATE**  
A degenerate polygon, i.e., all vertices equal or on the same line.

---

#### POLYGON\_CONVEX

private static final int **POLYGON\_CONVEX**  
A convex polygon.

---

#### POLYGON\_CONCAVE

private static final int **POLYGON\_CONCAVE**  
A concave polygon (simple or non-simple).

---

#### poly

private java.awt.Polygon **poly**  
The internal polygon.

---

#### clip

private java.awt.Rectangle **clip**  
The clipping Rectangle.

---

#### type

private int **type**  
The type of polygon.

---

#### insideRect

private boolean **insideRect**  
Flag indicating whether the Polygon is inside the supplied clipping Rectangle.

---

### Constructor Detail

## ROIShape.PolyShape

```
ROIShape.PolyShape(java.awt.Polygon polygon,  
                   java.awt.Rectangle clipRect)
```

Constructs a new PolyShape. The Polygon argument is clipped against the supplied Rectangle.

**Parameters:**

    polygon - The Polygon.  
    clipRect - The clipping Rectangle.

## Method Detail

### getAsRectList

```
public java.util.LinkedList getAsRectList()
```

Perform scan conversion of the PolyShape to generate a LinkedList of Rectangles.

**Returns:**

    A LinkedList of Rectangles representing the scan conversion of the PolyShape.

### classifyPolygon

```
private int classifyPolygon()
```

Classify a Polygon as one of the pre-defined types for this class.

### sgn

```
private int sgn(int i)
```

Calculate the sign of the argument.

**Parameters:**

    i - The integer the sign of which is to be determined.

**Returns:**

    1 for positive, -1 for negative, and 0 for zero arguments.

### scanConvex

```
private java.util.LinkedList scanConvex(java.util.LinkedList rectList)
```

Perform scan conversion of a convex polygon.

**Parameters:**

    rectList - A LinkedList; may be null.

**Returns:**

    A LinkedList of Rectangles representing the scan conversion of the convex polygon.

### scanSegment

```
private java.awt.Rectangle scanSegment(int y,  
                                       double leftX,  
                                       double rightX)
```

Return a Rectangle for the supplied line and abscissa end points.

**Parameters:**

    y - The line number.  
    leftX - The left end point of the segment.  
    rightX - The right end point of the segment.

**Returns:**

    The run length Rectangle for the segment.

### intersectX

```
private void intersectX(double x1,  
                       int y1,  
                       double x2,  
                       int y2,  
                       int y,  
                       double[] x,  
                       double[] dx)
```

For the line  $y + 0.5$  calculate the intersection with the segment  $(x1, y1)$  to  $(x2, y2)$  as well as the slope  $dx/dy$  at the point of intersection.

**Parameters:**

$x1$  - Abscissa of first segment end point.  
 $y1$  - Ordinate of first segment end point.  
 $x2$  - Abscissa of second segment end point.  
 $y2$  - Ordinate of second segment end point.  
 $y$  - The image line to intersect.  
 $x$  - The abscissa of the point of intersection.  
 $dx$  - The slope  $dx/dy$  of the point of intersection.

---

## scanConcave

```
private java.util.LinkedList scanConcave(java.util.LinkedList rectList)
```

Perform scan conversion of a concave polygon.

**Parameters:**

`rectList` - A LinkedList; may be null.

**Returns:**

A LinkedList of Rectangles representing the scan conversion of the concave polygon.

---

## deleteEdge

```
private void deleteEdge(java.util.Vector edges,  
                        int i)
```

Delete a PolyEdge from the Vector of active edges.

**Parameters:**

`edges` - The Vector of PolyEdges.  
`i` - The number of the edge to be deleted.

---

## appendEdge

```
private void appendEdge(java.util.Vector edges,  
                        int i,  
                        int y)
```

Append a PolyEdge to the Vector of active edges.

**Parameters:**

`edges` - The Vector of PolyEdges.  
`i` - The number of the edge to be appended.  
`y` - The y coordinate of the current scanline.

---

## intArrayToDoubleArray

```
private double[] intArrayToDoubleArray(int[] intArray)
```

Convert an array of ints to an array of doubles.

---

## vectorToIntArray

```
private int[] vectorToIntArray(java.util.Vector vector)
```

Convert a Vector of Integers to an array of ints.

**Parameters:**

`vector` - A Vector of Integers.

**Returns:**

The array of ints.

---

## javax.media.jai Class ROIShape

```
java.lang.Object
|
+-- javax.media.jai.ROI
|   |
|   +-- javax.media.jai.ROIShape
```

---

public class **ROIShape**  
extends ROI

A class representing a region of interest within an image as a Shape. Such regions are binary by definition. Using a Shape representation allows boolean operations to be performed quickly and with compact storage. If a PropertyGenerator responsible for generating the ROI property of a particular OperationDescriptor (e.g., a warp) cannot reasonably produce an ROIShape representing the region, it should call `getAsImage()` on its sources and produce its output ROI in image form.

---

### Field Detail

#### theShape

transient java.awt.Shape **theShape**  
The internal Shape that defines this mask.

### Constructor Detail

#### ROIShape

public **ROIShape**(java.awt.Shape s)  
Constructs an ROIShape from a Shape.  
**Parameters:**  
s - A Shape.  
**Throws:**  
java.lang.IllegalArgumentException - if s is null.

---

#### ROIShape

public **ROIShape**(java.awt.geom.Area a)  
Constructs an ROIShape from an Area.  
**Parameters:**  
a - An Area.

### Method Detail

#### getIntersection

```
private static java.awt.geom.Point2D.Double getIntersection(double x1,  
                                                             double y1,  
                                                             double x2,  
                                                             double y2,  
                                                             double u1,  
                                                             double v1,  
                                                             double u2,  
                                                             double v2)
```

Calculate the point of intersection of two line segments. This method assumes that the line segments do in fact intersect.

**Parameters:**

x1 - The abscissa of the first end point of the first segment.  
y1 - The ordinate of the first end point of the first segment.  
x2 - The abscissa of the second end point of the first segment.  
y2 - The ordinate of the second end point of the first segment.  
u1 - The abscissa of the first end point of the second segment.  
v1 - The ordinate of the first end point of the second segment.  
u2 - The abscissa of the second end point of the second segment.  
v2 - The ordinate of the second end point of the second segment.

**Returns:**

The point of intersection.

---

**polygonToRunLengthList**

```
private java.util.LinkedList polygonToRunLengthList(java.awt.Rectangle clip,  
                                                    java.awt.Polygon poly)
```

Convert a Polygon into a LinkedList of Rectangles representing run lengths of pixels contained within the Polygon.

**Parameters:**

clip - The clipping Rectangle.  
poly - The Polygon to examine.

**Returns:**

The LinkedList of run length Rectangles.

---

**rectangleListToBitmask**

```
private static int[][] rectangleListToBitmask(java.util.LinkedList rectangleList,  
                                              java.awt.Rectangle clip,  
                                              int[][] mask)
```

Convert a LinkedList of Rectangles into an array of integers representing a bit mask.

**Parameters:**

rectangleList - The list of Rectangles.  
clip - The clipping Rectangle.  
mask - A two-dimensional array of ints at least (width + 31)/32 entries wide and (height) entries tall, or null.

**Returns:**

An integer array representing a bit mask.

---

**getBounds**

```
public java.awt.Rectangle getBounds()
```

Returns the bounds of the mask as a Rectangle.

**Overrides:**

getBounds in class ROI

---

**getBounds2D**

```
public java.awt.geom.Rectangle2D getBounds2D()
```

Returns the bounds of the mask as a Rectangle2D.

**Overrides:**

getBounds2D in class ROI

---

**contains**

```
public boolean contains(java.awt.Point p)
```

Returns true if the mask contains a given Point.

**Parameters:**

p - a Point specifying the coordinates of the pixel to be queried.

**Returns:**

true if the pixel lies within the mask.

**Throws:**

NullPointerException - if p is null.

**Overrides:**

contains in class ROI

---

**contains**

```
public boolean contains(java.awt.geom.Point2D p)
```

Returns true if the mask contains a given Point2D.

**Parameters:**

p - A Point2D specifying the coordinates of the pixel to be queried.

**Returns:**  
true if the pixel lies within the mask.  
**Throws:**  
NullPointerException - is p is null.  
**Overrides:**  
contains in class ROI

---

## contains

```
public boolean contains(int x,  
                        int y)
```

Returns true if the mask contains the point (x, y).  
**Parameters:**  
x - An int specifying the X coordinate of the pixel to be queried.  
y - An int specifying the Y coordinate of the pixel to be queried.  
**Returns:**  
true if the pixel lies within the mask.  
**Overrides:**  
contains in class ROI

---

## contains

```
public boolean contains(double x,  
                        double y)
```

Returns true if the mask contains the point (x, y).  
**Parameters:**  
x - A double specifying the X coordinate of the pixel to be queried.  
y - A double specifying the Y coordinate of the pixel to be queried.  
**Returns:**  
true if the pixel lies within the mask.  
**Overrides:**  
contains in class ROI

---

## contains

```
public boolean contains(java.awt.Rectangle rect)
```

Returns true if a given Rectangle is entirely included within the mask.  
**Parameters:**  
rect - A Rectangle specifying the region to be tested for inclusion.  
**Returns:**  
true if the rectangle is entirely contained within the mask.  
**Throws:**  
NullPointerException - is rect is null.  
**Overrides:**  
contains in class ROI

---

## contains

```
public boolean contains(java.awt.geom.Rectangle2D rect)
```

Returns true if a given Rectangle2D is entirely included within the mask.  
**Parameters:**  
rect - A Rectangle2D specifying the region to be tested for inclusion.  
**Returns:**  
true if the rectangle is entirely contained within the mask.  
**Throws:**  
NullPointerException - is rect is null.  
**Overrides:**  
contains in class ROI

---

## contains

```
public boolean contains(int x,  
                        int y,  
                        int w,  
                        int h)
```

Returns true if a given rectangle (x, y, w, h) is entirely included within the mask.

**Parameters:**

x - The int X coordinate of the upper left corner of the region.  
y - The int Y coordinate of the upper left corner of the region.  
w - The int width of the region.  
h - The int height of the region.

**Returns:**

true if the rectangle is entirely contained within the mask.

**Overrides:**

contains in class ROI

---

## contains

```
public boolean contains(double x,  
                        double y,  
                        double w,  
                        double h)
```

Returns true if a given rectangle (x, y, w, h) is entirely included within the mask.

**Parameters:**

x - The double X coordinate of the upper left corner of the region.  
y - The double Y coordinate of the upper left corner of the region.  
w - The double width of the region.  
h - The double height of the region.

**Returns:**

true if the rectangle is entirely contained within the mask.

**Overrides:**

contains in class ROI

---

## intersects

```
public boolean intersects(java.awt.Rectangle r)
```

Returns true if a given Rectangle intersects the mask.

**Parameters:**

r - A Rectangle specifying the region to be tested for inclusion.

**Returns:**

true if the rectangle intersects the mask.

**Throws:**

NullPointerException - if r is null.

**Overrides:**

intersects in class ROI

---

## intersects

```
public boolean intersects(java.awt.geom.Rectangle2D r)
```

Returns true if a given Rectangle2D intersects the mask.

**Parameters:**

r - A Rectangle2D specifying the region to be tested for inclusion.

**Returns:**

true if the rectangle intersects the mask.

**Throws:**

NullPointerException - if r is null.

**Overrides:**

intersects in class ROI

---

## intersects

```
public boolean intersects(int x,  
                          int y,  
                          int w,  
                          int h)
```

Returns true if a given rectangle (x, y, w, h) intersects the mask.

**Parameters:**

x - The int X coordinate of the upper left corner of the region.  
y - The int Y coordinate of the upper left corner of the region.  
w - The int width of the region.  
h - The int height of the region.

**Returns:**

true if the rectangle intersects the mask.

**Overrides:**

intersects in class ROI

---

## intersects

```
public boolean intersects(double x,  
                          double y,  
                          double w,  
                          double h)
```

Returns true if a given rectangle (x, y, w, h) intersects the mask.

**Parameters:**

x - The double X coordinate of the upper left corner of the region.  
y - The double Y coordinate of the upper left corner of the region.  
w - The double width of the region.  
h - The double height of the region.

**Returns:**

true if the rectangle intersects the mask.

**Overrides:**

intersects in class ROI

---

## add

```
public ROI add(ROI roi)
```

Adds another mask to this one. This operation may force this mask to be rendered.

**Parameters:**

roi - A ROI.

**Throws:**

java.lang.IllegalArgumentException - is roi is null.

**Overrides:**

add in class ROI

---

## subtract

```
public ROI subtract(ROI roi)
```

Subtracts another mask from this one. This operation may force this mask to be rendered.

**Parameters:**

roi - A ROI.

**Throws:**

java.lang.IllegalArgumentException - is roi is null.

**Overrides:**

subtract in class ROI

---

## intersect

```
public ROI intersect(ROI roi)
```

Sets the mask to its intersection with another mask. This operation may force this mask to be rendered.

**Parameters:**

roi - A ROI.

**Throws:**

java.lang.IllegalArgumentException - is roi is null.

**Overrides:**  
intersect in class ROI

---

## exclusiveOr

public ROI **exclusiveOr**(ROI roi)

Sets the mask to its exclusive-or with another mask. This operation may force this mask to be rendered.

**Parameters:**

roi - A ROI.

**Throws:**

java.lang.IllegalArgumentException - is roi is null.

**Overrides:**

exclusiveOr in class ROI

---

## getAsShape

public java.awt.Shape **getAsShape**()

Returns the internal Shape representation or null if a shape representation is not possible.

**Overrides:**

getAsShape in class ROI

---

## getAsImage

public PlanarImage **getAsImage**()

Returns the shape as a PlanarImage. This requires performing an antialiased rendering of the internal Shape. A BufferedImage of type TYPE\_BYTE\_GRAY is used internally.

**Overrides:**

getAsImage in class ROI

---

## transform

public ROI **transform**(java.awt.geom.AffineTransform at)

Transforms the current contents of the ROI by a given AffineTransform.

**Parameters:**

at - An AffineTransform object.

**Throws:**

NullPointerException - if at is null.

**Overrides:**

transform in class ROI

---

## getAsBitmask

```
public int[][] getAsBitmask(int x,  
                             int y,  
                             int width,  
                             int height,  
                             int[][] mask)
```

Returns a bitmask for a given rectangular region of the ROI indicating whether the pixel is included in the region of interest. The results are packed into 32-bit integers, with the MSB considered to lie on the left. The last entry in each row of the result may have bits that lie outside of the requested rectangle. These bits are guaranteed to be zeroed.

The mask array, if supplied, must be of length equal to or greater than height and each of its subarrays must have length equal to or greater than (width + 31)/32. If null is passed in, a suitable array will be constructed. If the mask is non-null but has insufficient size, an exception will be thrown.

**Parameters:**

x - The X coordinate of the upper left corner of the rectangle.

y - The Y coordinate of the upper left corner of the rectangle.

width - The width of the rectangle.

height - The height of the rectangle.

mask - A two-dimensional array of ints at least (width + 31)/32 entries wide and (height) entries tall, or null.

**Returns:**

A reference to the mask parameter, or to a newly constructed array if mask is null.

**Overrides:**

getAsBitmask in class ROI

---

## getAsRectangleList

```
public java.util.LinkedList getAsRectangleList(int x,  
                                                int y,  
                                                int width,  
                                                int height)
```

Returns a LinkedList of Rectangles for a given rectangular region of the ROI. The Rectangles in the list are merged into a minimal set.

**Parameters:**

x - The X coordinate of the upper left corner of the rectangle.  
y - The Y coordinate of the upper left corner of the rectangle.  
width - The width of the rectangle.  
height - The height of the rectangle.

**Returns:**

A LinkedList of Rectangles.

**Overrides:**

getAsRectangleList in class ROI

---

## getAsRectangleList

```
protected java.util.LinkedList getAsRectangleList(int x,  
                                                    int y,  
                                                    int width,  
                                                    int height,  
                                                    boolean mergeRectangles)
```

Returns a LinkedList of Rectangles for a given rectangular region of the ROI.

**Parameters:**

x - The X coordinate of the upper left corner of the rectangle.  
y - The Y coordinate of the upper left corner of the rectangle.  
width - The width of the rectangle.  
height - The height of the rectangle.  
mergeRectangles - true if the Rectangles are to be merged into a minimal set.

**Returns:**

A LinkedList of Rectangles.

**Overrides:**

getAsRectangleList in class ROI

---

## writeObject

```
private void writeObject(java.io.ObjectOutputStream out)  
    throws java.io.IOException
```

Serialize the ROIShape.

**Parameters:**

out - The ObjectOutputStream.

**Overrides:**

writeObject in class ROI

---

## readObject

```
private void readObject(java.io.ObjectInputStream in)  
    throws java.io.IOException,  
           java.lang.ClassNotFoundException
```

Deserialize the ROIShape.

**Parameters:**

in - The ObjectInputStream.

**Overrides:**

readObject in class ROI

---

## javax.media.jai Class RasterAccessor

```
java.lang.Object
|
+-- javax.media.jai.RasterAccessor
```

---

public class **RasterAccessor**  
extends java.lang.Object

An adapter class for presenting image data in a ComponentSampleModel format, even if the data isn't stored that way. RasterAccessor is meant to make the common (ComponentSampleModel) case fast and other formats possible without forcing the OpImage writer to cover more than one case per data type.

---

### Field Detail

#### **COPY\_MASK\_SHIFT**

private static final int **COPY\_MASK\_SHIFT**

Value indicating how far COPY\_MASK info is shifted to avoid interfering with the data type info.

---

#### **COPY\_MASK\_SIZE**

private static final int **COPY\_MASK\_SIZE**

---

#### **COPY\_MASK**

public static final int **COPY\_MASK**

The bits of a FormatTag associated with how dataArrays are obtained.

---

#### **UNCOPIED**

public static final int **UNCOPIED**

Flag indicating data is raster's data.

---

#### **COPIED**

public static final int **COPIED**

Flag indicating data is a copy of the raster's data.

---

#### **EXPANSION\_MASK\_SHIFT**

private static final int **EXPANSION\_MASK\_SHIFT**

Value indicating how far EXPANSION\_MASK info is shifted to avoid interfering with the data type info.

---

#### **EXPANSION\_MASK\_SIZE**

private static final int **EXPANSION\_MASK\_SIZE**

Value indicating how many bits the EXPANSION\_MASK is

---

#### **EXPANSION\_MASK**

public static final int **EXPANSION\_MASK**

The bits of a FormatTag associated with how ColorModels are used.

---

## DEFAULTEXPANSION

public static final int **DEFAULTEXPANSION**

Flag indicating ColorModel data should be used only in copied case

---

## EXPANDED

public static final int **EXPANDED**

Flag indicating ColorModel data should be interpreted.

---

## UNEXPANDED

public static final int **UNEXPANDED**

Flag indicating ColorModel info should be ignored

---

## DATATYPE\_MASK

public static final int **DATATYPE\_MASK**

The bits of a FormatTagID associated with pixel datatype.

---

## TAG\_BYTE\_UNCOPIED

public static final int **TAG\_BYTE\_UNCOPIED**

FormatTagID indicating data in byte arrays and uncopied.

---

## TAG\_USHORT\_UNCOPIED

public static final int **TAG\_USHORT\_UNCOPIED**

FormatTagID indicating data in unsigned short arrays and uncopied.

---

## TAG\_SHORT\_UNCOPIED

public static final int **TAG\_SHORT\_UNCOPIED**

FormatTagID indicating data in short arrays and uncopied.

---

## TAG\_INT\_UNCOPIED

public static final int **TAG\_INT\_UNCOPIED**

FormatTagID indicating data in int arrays and uncopied.

---

## TAG\_FLOAT\_UNCOPIED

public static final int **TAG\_FLOAT\_UNCOPIED**

FormatTagID indicating data in float arrays and uncopied.

---

## TAG\_DOUBLE\_UNCOPIED

public static final int **TAG\_DOUBLE\_UNCOPIED**

FormatTagID indicating data in double arrays and uncopied.

---

## TAG\_INT\_COPIED

public static final int **TAG\_INT\_COPIED**

FormatTagID indicating data in int arrays and copied.

---

## **TAG\_FLOAT\_COPIED**

public static final int **TAG\_FLOAT\_COPIED**  
FormatTagID indicating data in float arrays and copied.

---

## **TAG\_DOUBLE\_COPIED**

public static final int **TAG\_DOUBLE\_COPIED**  
FormatTagID indicating data in double arrays and copied.

---

## **TAG\_BYTE\_EXPANDED**

public static final int **TAG\_BYTE\_EXPANDED**  
FormatTagID indicating data in byte arrays and uncopied.

---

## **raster**

protected java.awt.image.Raster **raster**  
The raster that is the source of pixel data.

---

## **rectWidth**

protected int **rectWidth**  
The width of the rectangle this RasterAccessor addresses.

---

## **rectHeight**

protected int **rectHeight**  
The height of the rectangle this RasterAccessor addresses.

---

## **rectX**

protected int **rectX**  
The x of the rectangle this RasterAccessor addresses.

---

## **rectY**

protected int **rectY**  
The y of the rectangle this RasterAccessor addresses.

---

## **formatTagID**

protected int **formatTagID**  
Tag indicating the data type of the data and whether its copied

---

## **byteDataArrays**

protected byte[][] **byteDataArrays**  
The image data in a two-dimensional byte array. This value will be non-null only if getDataTypes() returns DataBuffer.TYPE\_BYTE. byteDataArrays.length will equal numBands. Note that often the numBands subArrays will all point to the same place in memory.

---

## **shortDataArrays**

protected short[][] **shortDataArrays**  
The image data in a two-dimensional short array. This value will be non-null only if getDataTypes() returns DataBuffer.TYPE\_USHORT or DataBuffer.TYPE\_SHORT. shortDataArrays.length will equal numBands. Note that often the numBands subArrays will all point to the same place in memory.

---

## intDataArrays

protected int[][] **intDataArrays**

The image data in a two-dimensional int array. This value will be non-null only if `getDataType()` returns `DataBuffer.TYPE_INT`. `intDataArrays.length` will equal `numBands`. Note that often the `numBands` subArrays will all point to the same place in memory.

---

## floatDataArrays

protected float[][] **floatDataArrays**

The image data in a two-dimensional float array. This value will be non-null only if `getDataType()` returns `DataBuffer.TYPE_FLOAT`. `floatDataArrays.length` will equal `numBands`. Note that often the `numBand` subArrays will all point to the same place in memory.

---

## doubleDataArrays

protected double[][] **doubleDataArrays**

The image data in a two-dimensional double array. This value will be non-null only if `getDataType()` returns `DataBuffer.TYPE_DOUBLE`. `doubleDataArrays.length` will equal `numBands`. Note that often the `numBand` subArrays will all point to the same place in memory.

---

## bandDataOffsets

protected int[] **bandDataOffsets**

The `bandOffset` + `subRasterOffset` + `DataBufferOffset` into each of the `numBand` data arrays

---

## bandOffsets

protected int[] **bandOffsets**

Offset from a pixel's offset to a band of that pixel

---

## numBands

protected int **numBands**

The number of bands per pixel in the data array.

---

## scanlineStride

protected int **scanlineStride**

The scanline stride of the image data in each data array

---

## pixelStride

protected int **pixelStride**

The pixel stride of the image data in each data array

---

## Constructor Detail

### RasterAccessor

```
public RasterAccessor( java.awt.image.Raster raster,
                      java.awt.Rectangle rect,
                      RasterFormatTag rft,
                      java.awt.image.ColorModel theColorModel)
```

Constructs a `RasterAccessor` object out of a `Raster`, `Rectangle` and `formatTagID` returned from `RasterFormat.findCompatibleTag()`.

The `RasterFormatTag` must agree with the raster's `SampleModel` and `ColorModel`. It is best to obtain the correct tag using the `findCompatibleTags` static method.

#### Throws:

`ClassCastException` - if the data type of `RasterFormatTag` does not agree with the actual data type of the `Raster`.

## Method Detail

### findCompatibleTags

```
public static RasterFormatTag[] findCompatibleTags(java.awt.image.RenderedImage[] srcs,  
                                                    java.awt.image.RenderedImage dst)
```

Finds the appropriate tags for the constructor, based on the SampleModel and ColorModel of all the source and destination.

### findCompatibleTag

```
public static int findCompatibleTag(java.awt.image.SampleModel[] srcSampleModels,  
                                     java.awt.image.SampleModel dstSampleModel)
```

Returns the most efficient FormatTagID that is compatible with the destination SampleModel and all source SampleModel. Since there is no ColorModel associated with a SampleModel, this method does not expand the data buffer as it has no access to the Raster's ColorModel.

### getX

```
public int getX()
```

Returns the x coordinate of the upper-left corner of the RasterAccessor's accessible area.

### getY

```
public int getY()
```

Returns the y coordinate of the upper-left corner of the RasterAccessor's accessible area.

### getWidth

```
public int getWidth()
```

Returns the width of the RasterAccessor's accessible area.

### getHeight

```
public int getHeight()
```

Returns the height of the RasterAccessor's accessible area.

### getNumBands

```
public int getNumBands()
```

Returns the numBands of the presented area.

### getBytesDataArrays

```
public byte[][] getBytesDataArrays()
```

Returns the image data as a byte array. Non-null only if getDataType = DataBuffer.TYPE\_BYTE.

### getBytesDataArray

```
public byte[] getBytesDataArray(int b)
```

Returns the image data as a byte array for a specific band. Non-null only if getDataType = DataBuffer.TYPE\_BYTE.

### getShortDataArrays

```
public short[][] getShortDataArrays()
```

Returns the image data as a short array. Non-null only if getDataType = DataBuffer.TYPE\_USHORT or DataBuffer.TYPE\_SHORT.

### **getShortDataArray**

public short[] **getShortDataArray**(int b)

Returns the image data as a short array for a specific band. Non-null only if `getDataType = DataBuffer.TYPE_USHORT` or `DataBuffer.TYPE_SHORT`.

---

### **getIntDataArrays**

public int[][] **getIntDataArrays**()

Returns the image data as an int array. Non-null only if `getDataType = DataBuffer.TYPE_INT`.

---

### **getIntDataArray**

public int[] **getIntDataArray**(int b)

Returns the image data as an int array for a specific band. Non-null only if `getDataType = DataBuffer.TYPE_INT`.

---

### **getFloatDataArrays**

public float[][] **getFloatDataArrays**()

Returns the image data as a float array. Non-null only if `getDataType = DataBuffer.TYPE_FLOAT`.

---

### **getFloatDataArray**

public float[] **getFloatDataArray**(int b)

Returns the image data as a float array for a specific band. Non-null only if `getDataType = DataBuffer.TYPE_FLOAT`.

---

### **getDoubleDataArrays**

public double[][] **getDoubleDataArrays**()

Returns the image data as a double array. Non-null only if `getDataType = DataBuffer.TYPE_DOUBLE`

---

### **getDoubleDataArray**

public double[] **getDoubleDataArray**(int b)

Returns the image data as a double array for a specific band. Non-null only if `getDataType = DataBuffer.TYPE_DOUBLE`

---

### **getDataArray**

public java.lang.Object **getDataArray**(int b)

Returns the image data as an Object for a specific band.

**Parameters:**

b - The index of the image band of interest.

**Returns:**

The data array for the requested band.

**Throws:**

ArrayIndexOutOfBoundsException - if b is out of bounds.

---

### **getBandOffsets**

public int[] **getBandOffsets**()

Returns the bandDataOffsets into the dataArrays.

---

### **getOffsetsForBands**

public int[] **getOffsetsForBands**()

Returns the offset of all band's samples from any pixel offset.

**Throws:**

ArrayIndexOutOfBoundsException - if b is out of bounds.

---

## getBandOffset

public int **getBandOffset**(int b)

Returns the offset of a specific band's first sample into the DataBuffer including the DataBuffer's offset.

**Throws:**

ArrayIndexOutOfBoundsException - if b is out of bounds.

---

## getOffsetForBand

public int **getOffsetForBand**(int b)

Returns the offset of a specified band's sample from any pixel offset.

**Throws:**

ArrayIndexOutOfBoundsException - if b is out of bounds.

---

## getScanlineStride

public int **getScanlineStride**()

Returns the scanlineStride for the image data.

---

## getPixelStride

public int **getPixelStride**()

Returns the pixelStride for the image data.

---

## getDataType

public int **getDataType**()

Returns the data type of the RasterAccessor object. Note that this datatype is not necessarily the same data type as the underlying raster.

---

## isDataCopy

public boolean **isDataCopy**()

Returns true if the RasterAccessors's data is copied from it's raster.

---

## copyDataToRaster

public void **copyDataToRaster**()

Copies data back into the RasterAccessor's raster. Note that the data is cast from the intermediate data format to the raster's format. If clamping is needed, the call clampDataArrays() method needs to be called before calling the copyDataToRaster() method.

---

## needsClamping

public boolean **needsClamping**()

Indicates if the RasterAccessor has a larger dynamic range than the underlying Raster. Except in special cases, where the op knows something special, this call will determine whether or not clampDataArrays() needs to be called.

---

## clampDataArrays

public void **clampDataArrays**()

Clamps data array values to a range that the underlying raster can deal with. For example, if the underlying raster stores data as bytes, but the samples are unpacked into integer arrays by the RasterAccessor for an operation, the operation will need to call clampDataArrays() so that the data in the int arrays is restricted to the range 0..255 before a setPixels() call is made on the underlying raster. Note that some operations (for example, lookup) can guarantee that their results don't need clamping so they can call RasterAccessor.copyDataToRaster() without first calling this function.

---

### **clampDataArray**

```
private void clampDataArray(double[] hiVals,  
                             double[] loVals)
```

---

### **toIntArray**

```
private int[] toIntArray(double[] vals)
```

---

### **toFloatArray**

```
private float[] toFloatArray(double[] vals)
```

---

### **clampIntArray**

```
private void clampIntArray(int[] hiVals,  
                             int[] loVals)
```

---

### **clampFloatArrays**

```
private void clampFloatArrays(float[] hiVals,  
                                float[] loVals)
```

---

### **clampDoubleArrays**

```
private void clampDoubleArrays(double[] hiVals,  
                                double[] loVals)
```

---

## javax.media.jai Class RasterFactory

```
java.lang.Object
|
+-- javax.media.jai.RasterFactory
```

---

public class **RasterFactory**  
extends java.lang.Object

A convenience class for the construction of various types of WritableRaster and SampleModel objects.

This class provides the capability of creating Rasters with the enumerated data types in the java.awt.image.DataBuffer.

In some cases, instances of ComponentSampleModelJAI, a subclass of java.awt.image.ComponentSampleModel are instantiated instead of java.awt.image.BandedSampleModel in order to work around bugs in the current release of the Java 2 SDK.

---

### Constructor Detail

#### RasterFactory

public **RasterFactory**()

### Method Detail

#### createInterleavedRaster

```
public static java.awt.image.WritableRaster createInterleavedRaster(int dataType,
                                                                    int width,
                                                                    int height,
                                                                    int numBands,
                                                                    java.awt.Point location)
```

Creates a WritableRaster based on a PixelInterleavedSampleModel with the specified data type, width, height, and number of bands.

The upper left corner of the WritableRaster is given by the location argument. If location is null, (0, 0) will be used. The dataType parameter should be one of the enumerated values defined in the DataBuffer class.

**Parameters:**

dataType - The data type of the SampleModel, one of DataBuffer.TYPE\_BYTE, TYPE\_USHORT, TYPE\_SHORT, TYPE\_INT, TYPE\_FLOAT, or TYPE\_DOUBLE.

width - The desired width of the WritableRaster.

height - The desired height of the WritableRaster.

numBands - The desired number of bands.

location - A Point indicating the starting coordinates of the WritableRaster.

**Throws:**

java.lang.IllegalArgumentException - if numbands is <1.

---

#### createInterleavedRaster

```
public static java.awt.image.WritableRaster createInterleavedRaster(int dataType,
                                                                    int width,
                                                                    int height,
                                                                    int scanlineStride,
                                                                    int pixelStride,
                                                                    int[] bandOffsets,
                                                                    java.awt.Point location)
```

Creates a WritableRaster based on a PixelInterleavedSampleModel with the specified data type, width, height, scanline stride, pixel stride, and band offsets. The number of bands is inferred from bandOffsets.length.

The upper left corner of the WritableRaster is given by the location argument. If location is null, (0, 0) will be used. The dataType parameter should be one of the enumerated values defined in the DataBuffer class.

**Parameters:**

dataType - The data type of the WritableRaster, one of the enumerated dataType values in java.awt.image.DataBuffer.

width - The desired width of the WritableRaster.

height - The desired height of the WritableRaster.

scanlineStride - The desired scanline stride.

pixelStride - The desired pixel stride.

bandOffsets - An array of ints indicating the relative offsets of the bands within a pixel.  
location - A Point indicating the starting coordinates of the WritableRaster.

**Throws:**

java.lang.IllegalArgumentException - if bandOffsets is null, dataType is not one of the enumerated dataType value of java.awt.image.DataBuffer.  
java.lang.IllegalArgumentException - if the number of array elements required by the returned WritableRaster would exceed Integer.MAX\_VALUE.

---

## createBandedRaster

```
public static java.awt.image.WritableRaster createBandedRaster(int dataType,
                                                             int width,
                                                             int height,
                                                             int bands,
                                                             java.awt.Point location)
```

Creates a WritableRaster based on a ComponentSampleModel with the specified data type, width, height, and number of bands.

Note that the Raster's SampleModel will be of type ComponentSampleModel, not BandedSampleModel as might be expected.

The upper left corner of the WritableRaster is given by the location argument. If location is null, (0, 0) will be used. The dataType parameter should be one of the enumerated values defined in the DataBuffer class.

**Parameters:**

dataType - The data type of the WritableRaster, one of the enumerated dataType values in java.awt.image.DataBuffer.  
width - The desired width of the WritableRaster.  
height - The desired height of the WritableRaster.  
bands - The desired number of bands.  
location - A Point indicating the starting coordinates of the WritableRaster.

**Throws:**

java.lang.IllegalArgumentException - if bands is <1.

---

## createBandedRaster

```
public static java.awt.image.WritableRaster createBandedRaster(int dataType,
                                                             int width,
                                                             int height,
                                                             int scanlineStride,
                                                             int[] bankIndices,
                                                             int[] bandOffsets,
                                                             java.awt.Point location)
```

Creates a WritableRaster based on a ComponentSampleModel with the specified data type, width, height, scanline stride, bank indices and band offsets. The number of bands is inferred from bankIndices.length and bandOffsets.length, which must be the same.

Note that the Raster's SampleModel will be of type ComponentSampleModel, not BandedSampleModel as might be expected.

The upper left corner of the WritableRaster is given by the location argument. The dataType parameter should be one of the enumerated values defined in the DataBuffer class.

**Parameters:**

dataType - The data type of the WritableRaster, one of the enumerated dataType values in java.awt.image.DataBuffer.  
width - The desired width of the WritableRaster.  
height - The desired height of the WritableRaster.  
scanlineStride - The desired scanline stride.  
bankIndices - An array of ints indicating the bank index for each band.  
bandOffsets - An array of ints indicating the relative offsets of the bands within a pixel.  
location - A Point indicating the starting coordinates of the WritableRaster.

**Throws:**

java.lang.IllegalArgumentException - if bankIndices is null, bandOffsets is null, if bandOffsets.length is != bankIndices.length, if dataType is not one of the enumerated datatypes of java.awt.image.DataBuffer.

---

## createPackedRaster

```
public static java.awt.image.WritableRaster createPackedRaster(int dataType,
                                                             int width,
                                                             int height,
                                                             int[] bandMasks,
                                                             java.awt.Point location)
```

Creates a `WritableRaster` based on a `SinglePixelPackedSampleModel` with the specified data type, width, height, and band masks. The number of bands is inferred from `bandMasks.length`.

The upper left corner of the `WritableRaster` is given by the `location` argument. If `location` is null, (0, 0) will be used. The `dataType` parameter should be one of the enumerated values defined in the `DataBuffer` class.

### Parameters:

`dataType` - The data type of the `WritableRaster`, one of `DataBuffer.TYPE_BYTE`, `TYPE_USHORT` or `TYPE_INT`.

`width` - The desired width of the `WritableRaster`.

`height` - The desired height of the `WritableRaster`.

`location` - A `Point` indicating the starting coordinates of the `WritableRaster`.

### Throws:

`java.lang.IllegalArgumentException` - is thrown if the `dataType` is not of either `TYPE_BYTE` or `TYPE_USHORT` or `TYPE_INT`.

---

## createPackedRaster

```
public static java.awt.image.WritableRaster createPackedRaster(int dataType,
                                                             int width,
                                                             int height,
                                                             int numBands,
                                                             int bitsPerBand,
                                                             java.awt.Point location)
```

Creates a `WritableRaster` based on a packed `SampleModel` with the specified data type, width, height, number of bands, and bits per band. If the number of bands is one, the `SampleModel` will be a `MultiPixelPackedSampleModel`.

If the number of bands is more than one, the `SampleModel` will be a `SinglePixelPackedSampleModel`, with each band having `bitsPerBand` bits. In either case, the requirements on `dataType` and `bitsPerBand` imposed by the corresponding `SampleModel` must be met.

The upper left corner of the `WritableRaster` is given by the `location` argument. If `location` is null, (0, 0) will be used. The `dataType` parameter should be one of the enumerated values defined in the `DataBuffer` class.

### Parameters:

`dataType` - The data type of the `WritableRaster`, one of `DataBuffer.TYPE_BYTE`, `TYPE_USHORT` or `TYPE_INT`.

`width` - The desired width of the `WritableRaster`.

`height` - The desired height of the `WritableRaster`.

`numBands` - The desired number of bands.

`bitsPerBand` - The number of bits per band.

`location` - A `Point` indicating the starting coordinates of the `WritableRaster`.

### Throws:

`java.lang.IllegalArgumentException` - is thrown if the `dataType` is not of either `TYPE_BYTE` or `TYPE_USHORT` or `TYPE_INT`.

`java.lang.IllegalArgumentException` - is thrown if `bitsPerBand` is negative or zero.

---

## createInterleavedRaster

```
public static java.awt.image.WritableRaster createInterleavedRaster(java.awt.image.DataBuffer dataBuffer,
                                                                    int width,
                                                                    int height,
                                                                    int scanlineStride,
                                                                    int pixelStride,
                                                                    int[] bandOffsets,
                                                                    java.awt.Point location)
```

Creates a `WritableRaster` based on a `PixelInterleavedSampleModel` with the specified `DataBuffer`, width, height, scanline stride, pixel stride, and band offsets. The number of bands is inferred from `bandOffsets.length`. The upper left corner of the `WritableRaster` is given by the `location` argument. If `location` is null, (0, 0) will be used.

### Parameters:

`dataBuffer` - The `DataBuffer` to be used.

`width` - The desired width of the `WritableRaster`.

`height` - The desired height of the `WritableRaster`.

`scanlineStride` - The desired scanline stride.

pixelStride - The desired pixel stride.  
bandOffsets - An array of ints indicating the relative offsets of the bands within a pixel.  
location - A Point indicating the starting coordinates of the WritableRaster.

**Throws:**

java.lang.IllegalArgumentException - if bandOffsets is null, if pixelStride\*width is > scanlineStride, if dataType of the DataBuffer is not one of the enumerated dataType values of java.awt.image.DataBuffer.

---

## createBandedRaster

```
public static java.awt.image.WritableRaster createBandedRaster(java.awt.image.DataBuffer dataBuffer,  
                                                             int width,  
                                                             int height,  
                                                             int scanlineStride,  
                                                             int[] bankIndices,  
                                                             int[] bandOffsets,  
                                                             java.awt.Point location)
```

Creates a WritableRaster based on a ComponentSampleModel with the specified DataBuffer, width, height, scanline stride, bank indices, and band offsets. The number of bands is inferred from bankIndices.length and bandOffsets.length, which must be the same. The upper left corner of the WritableRaster is given by the location argument. If location is null, (0, 0) will be used.

Note that the Raster's SampleModel will be of type ComponentSampleModel, not BandedSampleModel as might be expected.

**Parameters:**

dataBuffer - The DataBuffer to be used.  
width - The desired width of the WritableRaster.  
height - The desired height of the WritableRaster.  
scanlineStride - The desired scanline stride.  
bankIndices - An array of ints indicating the bank index for each band.  
bandOffsets - An array of ints indicating the relative offsets of the bands within a pixel.  
location - A Point indicating the starting coordinates of the WritableRaster.

**Throws:**

java.lang.IllegalArgumentException - if bankIndices is null, if bandOffsets is null, if bandOffsets.length is != bankIndices.length, if dataType is not one of the enumerated datatypes of java.awt.image.DataBuffer.

---

## createPackedRaster

```
public static java.awt.image.WritableRaster createPackedRaster(java.awt.image.DataBuffer dataBuffer,  
                                                             int width,  
                                                             int height,  
                                                             int scanlineStride,  
                                                             int[] bandMasks,  
                                                             java.awt.Point location)
```

Creates a WritableRaster based on a SinglePixelPackedSampleModel with the specified DataBuffer, width, height, scanline stride, and band masks. The number of bands is inferred from bandMasks.length. The upper left corner of the WritableRaster is given by the location argument. If location is null, (0, 0) will be used.

**Parameters:**

dataBuffer - The DataBuffer to be used.  
width - The desired width of the WritableRaster.  
height - The desired height of the WritableRaster.  
scanlineStride - The desired scanline stride.  
bandMasks - An array of ints indicating the bitmasks for each band within a pixel.  
location - A Point indicating the starting coordinates of the WritableRaster.

**Throws:**

java.lang.IllegalArgumentException - is thrown if the dataType is not of either TYPE\_BYTE or TYPE\_USHORT or TYPE\_INT.

---

## createPackedRaster

```
public static java.awt.image.WritableRaster createPackedRaster(java.awt.image.DataBuffer dataBuffer,  
                                                             int width,  
                                                             int height,  
                                                             int bitsPerPixel,  
                                                             java.awt.Point location)
```

Creates a `WritableRaster` based on a `MultiPixelPackedSampleModel` with the specified `DataBuffer`, width, height, and bits per pixel. The upper left corner of the `WritableRaster` is given by the `location` argument. If `location` is null, (0, 0) will be used.

**Parameters:**

`dataBuffer` - The `DataBuffer` to be used.  
`width` - The desired width of the `WritableRaster`.  
`height` - The desired height of the `WritableRaster`.  
`bitsPerPixel` - The desired pixel depth.  
`location` - A `Point` indicating the starting coordinates of the `WritableRaster`.

**Throws:**

`java.lang.IllegalArgumentException` - is thrown if the `dataType` of the `dataBuffer` is not of either `TYPE_BYTE` or `TYPE_USHORT` or `TYPE_INT`.

---

## createRaster

```
public static java.awt.image.Raster createRaster(java.awt.image.SampleModel sampleModel,
                                                java.awt.image.DataBuffer dataBuffer,
                                                java.awt.Point location)
```

Creates a `WritableRaster` with the specified `SampleModel` and `DataBuffer`. The upper left corner of the `WritableRaster` is given by the `location` argument. If `location` is null, (0, 0) will be used.

**Parameters:**

`sampleModel` - The `SampleModel` to be used.  
`dataBuffer` - The `DataBuffer` to be used.  
`location` - A `Point` indicating the starting coordinates of the `WritableRaster`.

---

## createWritableRaster

```
public static java.awt.image.WritableRaster createWritableRaster(java.awt.image.SampleModel sampleModel,
                                                                java.awt.Point location)
```

Creates a `WritableRaster` with the specified `SampleModel`. The upper left corner of the `WritableRaster` is given by the `location` argument. If `location` is null, (0, 0) will be used.

**Parameters:**

`sampleModel` - The `SampleModel` to use.  
`location` - A `Point` indicating the starting coordinates of the `WritableRaster`.

---

## createWritableRaster

```
public static java.awt.image.WritableRaster createWritableRaster(java.awt.image.SampleModel sampleModel,
                                                                java.awt.image.DataBuffer dataBuffer,
                                                                java.awt.Point location)
```

Creates a `WritableRaster` with the specified `SampleModel` and `DataBuffer`. The upper left corner of the `WritableRaster` is given by the `location` argument. If `location` is null, (0, 0) will be used.

**Parameters:**

`sampleModel` - The `SampleModel` to be used.  
`dataBuffer` - The `DataBuffer` to be used.  
`location` - A `Point` indicating the starting coordinates of the `WritableRaster`.

---

## createWritableChild

```
public static java.awt.image.WritableRaster createWritableChild(java.awt.image.WritableRaster raster,
                                                                int parentX,
                                                                int parentY,
                                                                int width,
                                                                int height,
                                                                int childMinX,
                                                                int childMinY,
                                                                int[] bandList)
```

Returns a new `WritableRaster` which shares all or part of the supplied `WritableRaster`'s `DataBuffer`. The new `WritableRaster` will possess a reference to the supplied `WritableRaster`, accessible through its `getParent()` and `getWritableParent()` methods. This method provides a workaround for a bug in the implementation of `WritableRaster.createWritableChild` in the initial release of the Java2 platform.

The `parentX`, `parentY`, `width` and `height` parameters form a `Rectangle` in this `WritableRaster`'s coordinate space, indicating the area of pixels to be shared. An error will be thrown if this `Rectangle` is not contained within the bounds of the supplied `WritableRaster`.

The new `WritableRaster` may additionally be translated to a different coordinate system for the plane than that used by the supplied `WritableRaster`. The `childMinX` and `childMinY` parameters give the new (x, y) coordinate of the upper-left pixel of the returned `WritableRaster`; the coordinate (`childMinX`, `childMinY`) in the new `WritableRaster` will map to the same pixel as the coordinate (`parentX`, `parentY`) in the supplied `WritableRaster`.

The new `WritableRaster` may be defined to contain only a subset of the bands of the supplied `WritableRaster`, possibly reordered, by means of the `bandList` parameter. If `bandList` is null, it is taken to include all of the bands of the supplied `WritableRaster` in their current order.

To create a new `WritableRaster` that contains a subregion of the supplied `WritableRaster`, but shares its coordinate system and bands, this method should be called with `childMinX` equal to `parentX`, `childMinY` equal to `parentY`, and `bandList` equal to null.

**Parameters:**

`raster` - The parent `WritableRaster`.  
`parentX` - X coordinate of the upper left corner of the shared rectangle in this `WritableRaster`'s coordinates.  
`parentY` - Y coordinate of the upper left corner of the shared rectangle in this `WritableRaster`'s coordinates.  
`width` - Width of the shared rectangle starting at (`parentX`, `parentY`).  
`height` - Height of the shared rectangle starting at (`parentX`, `parentY`).  
`childMinX` - X coordinate of the upper left corner of the returned `WritableRaster`.  
`childMinY` - Y coordinate of the upper left corner of the returned `WritableRaster`.  
`bandList` - Array of band indices, or null to use all bands.

**Throws:**

`java.awt.image.RasterFormatException` - if the subregion is outside of the raster bounds.

---

## createBandedSampleModel

```
public static java.awt.image.SampleModel createBandedSampleModel(int dataType,
                                                                int width,
                                                                int height,
                                                                int numBands,
                                                                int[] bankIndices,
                                                                int[] bandOffsets)
```

Creates a banded `SampleModel` with a given data type, width, height, number of bands, bank indices, and band offsets.

Note that the returned `SampleModel` will be of type `ComponentSampleModel`, not `BandedSampleModel` as might be expected. Its behavior will be equivalent to that of a `BandedSampleModel`, and in particular its pixel stride will always be 1.

**Parameters:**

`dataType` - The data type of the `SampleModel`, one of `DataBuffer.TYPE_BYTE`, `TYPE_USHORT`, `TYPE_SHORT`, `TYPE_INT`, `TYPE_FLOAT`, or `TYPE_DOUBLE`.  
`width` - The desired width of the `SampleModel`.  
`height` - The desired height of the `SampleModel`.  
`numBands` - The desired number of bands.  
`bankIndices` - An array of ints indicating the bank index for each band.  
`bandOffsets` - An array of ints indicating the relative offsets of the bands within a pixel.

**Throws:**

`java.lang.IllegalArgumentException` - if `numBands` is <1, if `bandOffsets.length` is != `bankIndices.length`.

---

## createBandedSampleModel

```
public static java.awt.image.SampleModel createBandedSampleModel(int dataType,
                                                                int width,
                                                                int height,
                                                                int numBands)
```

Creates a banded `SampleModel` with a given data type, width, height, and number of bands. The bank indices and band offsets are set to default values.

Note that the returned `SampleModel` will be of type `ComponentSampleModel`, not `BandedSampleModel` as might be expected. Its behavior will be equivalent to that of a `BandedSampleModel`, and in particular its pixel stride will always be 1.

**Parameters:**

`dataType` - The data type of the `SampleModel`, one of `DataBuffer.TYPE_BYTE`, `TYPE_USHORT`, `TYPE_SHORT`, `TYPE_INT`, `TYPE_FLOAT`, or `TYPE_DOUBLE`.  
`width` - The desired width of the `SampleModel`.  
`height` - The desired height of the `SampleModel`.  
`numBands` - The desired number of bands.

---

## createPixelInterleavedSampleModel

```
public static java.awt.image.SampleModel createPixelInterleavedSampleModel(int dataType,
                                                                           int width,
                                                                           int height,
                                                                           int pixelStride,
                                                                           int scanlineStride,
                                                                           int[] bandOffsets)
```

Creates a pixel interleaved `SampleModel` with a given data type, width, height, pixel and scanline strides, and band offsets.

### Parameters:

`dataType` - The data type of the `SampleModel`, one of `DataBuffer.TYPE_BYTE`, `TYPE_USHORT`, `TYPE_SHORT`, `TYPE_INT`, `TYPE_FLOAT`, or `TYPE_DOUBLE`.  
`width` - The desired width of the `SampleModel`.  
`height` - The desired height of the `SampleModel`.  
`pixelStride` - The desired pixel stride.  
`scanlineStride` - The desired scanline stride.  
`bandOffsets` - An array of ints indicating the relative offsets of the bands within a pixel.

### Throws:

`java.lang.IllegalArgumentException` - if `bandOffsets` is null, if the `pixelStride*width` is > than `scanlineStride`, if the `dataType` is not one of the above mentioned datatypes.

---

## createPixelInterleavedSampleModel

```
public static java.awt.image.SampleModel createPixelInterleavedSampleModel(int dataType,
                                                                           int width,
                                                                           int height,
                                                                           int numBands)
```

Creates a pixel interleaved `SampleModel` with a given data type, width, height, and number of bands. The pixel stride, scanline stride, and band offsets are set to default values.

### Parameters:

`dataType` - The data type of the `SampleModel`, one of `DataBuffer.TYPE_BYTE`, `TYPE_USHORT`, `TYPE_SHORT`, `TYPE_INT`, `TYPE_FLOAT`, or `TYPE_DOUBLE`.  
`width` - The desired width of the `SampleModel`.  
`height` - The desired height of the `SampleModel`.  
`numBands` - The desired number of bands.

### Throws:

`java.lang.IllegalArgumentException` - if `numBands` is <1.

---

## createComponentSampleModel

```
public static java.awt.image.SampleModel createComponentSampleModel(java.awt.image.SampleModel sm,
                                                                     int dataType,
                                                                     int width,
                                                                     int height,
                                                                     int numBands)
```

Creates a component `SampleModel` with a given data type, width, height, and number of bands that is "compatible" with a given `SampleModel`.

### Parameters:

`sm` - The `SampleModel` to be compatible with.  
`dataType` - The data type of the `SampleModel`, one of `DataBuffer.TYPE_BYTE`, `TYPE_USHORT`, `TYPE_SHORT`, `TYPE_INT`, `TYPE_FLOAT`, or `TYPE_DOUBLE`.  
`width` - The desired width of the `SampleModel`.  
`height` - The desired height of the `SampleModel`.  
`numBands` - The desired number of bands.

---

## createComponentColorModel

```
public static java.awt.image.ColorModel createComponentColorModel(int dataType,
                                                                    java.awt.color.ColorSpace colorSpace,
                                                                    boolean useAlpha,
                                                                    boolean premultiplied,
                                                                    int transparency)
```

Creates a component-based `ColorModel` with a given data type, color space, and transparency type. Currently this method does not support data type `DataBuffer.TYPE_SHORT`.

**Parameters:**

`dataType` - The data type of the `ColorModel`, one of `DataBuffer.TYPE_BYTE`, `TYPE_USHORT`, `TYPE_INT`, `TYPE_FLOAT`, or `TYPE_DOUBLE`.

`colorSpace` - An instance of `ColorSpace`.

`useAlpha` - true if alpha is to be used.

`premultiplied` - true if alpha values are premultiplied. If `useAlpha` is false, the value of `premultiplied` is ignored.

`transparency` - One of `Transparency.OPAQUE`, `Transparency.BITMASK`, or `Transparency.TRANSLUCENT`. If `useAlpha` is false, the value of `transparency` is ignored. If `useAlpha` is true, `transparency` must not equal `Transparency.OPAQUE`.

**Throws:**

`NullPointerException` - if `colorSpace` is null.

`java.lang.IllegalArgumentException` - if `transparency` has an unknown value, if `useAlpha == true` but `transparency == Transparency.OPAQUE`, or if `dataType` is not one of the standard types listed above.

---

## javax.media.jai Class RasterFormatTag

java.lang.Object

|-- javax.media.jai.RasterFormatTag

---

public final class **RasterFormatTag**  
extends java.lang.Object

This class encapsulates the information needed for RasterAccessor to understand how a Raster is laid out. It's designed so that one RasterFormatTag can be constructed per source and that RasterFormatTag can cache information that the RasterAccessor would otherwise have to extract from the Raster each time it's constructed (generally each time OpImage.computeRect() is called.) Additionally, it can cache various arrays (i.e. bankIndices[] and bandOffsets[]) that that would otherwise be cloned everytime they were requested. Because of the way SampleModel.createCompatibleSampleModel() is designed not all fields of a particular SampleModel will match those of the SampleModel returned by SampleModel.createCompatibleSampleModel(). Values like pixelStride and numBands won't change, but values like bankIndices[] and bandOffsets[] might if the underlying Raster is not pixelSequential. Rasters which are pixelSequential meet the following conditions 1) The SampleModel is a ComponentSampleModel. 2) The pixelStride is equal to the number of bands. 3) All the bankIndices[] are equal. 4) All the bandOffsets[] values are less than pixelStride 5) No two bandOffsets[] values are equal. For that reason, RasterFormatTags representing non pixelSequential rasters don't attempt to cache the bandOffsets[] or bankIndices[]. For such rasters, this information should be taken directly from the raster itself. Note that any RasterFormatTag that will cause data to be copied from the Raster will be pixelSequential as that is the format in which data is returned from Raster.getPixels() returns.

---

### Field Detail

#### **COPY\_MASK**

private static final int **COPY\_MASK**

---

#### **UNCOPIED**

private static final int **UNCOPIED**

---

#### **COPIED**

private static final int **COPIED**

---

#### **formatTagID**

private int **formatTagID**

---

#### **bankIndices**

private int[] **bankIndices**

---

#### **numBands**

private int **numBands**

---

#### **bandOffsets**

private int[] **bandOffsets**

---

#### **pixelStride**

private int **pixelStride**

---

## isPixelSequential

```
private boolean isPixelSequential
```

### Constructor Detail

## RasterFormatTag

```
public RasterFormatTag(java.awt.image.SampleModel sampleModel,  
                        int formatTagID)
```

Constructs a RasterFormatTag given a sampleModel and a formatTagID. Generally, this constructor is called by RasterAccessor.findCompatibleTags(RenderedImage[] srcs, RenderedImage dst) and it takes care of setting the values correctly. In special cases, OpImages need to construct a RasterFormatTag without creating a RenderedImage. In this case a RasterFormatTag can be created using a formatTagID returned from RasterAccessor.findCompatibleTag(SampleModel[] srcs, SampleModel dst) and a sampleModel that was either passed in to the findCompatibleTag() call or one that was created using createCompatibleSampleModel() on one of the passed in SampleModels. Attempting to use arbitrary SampleModels with arbitrary formatTagIDs has undefined results.

### Method Detail

## isPixelSequential

```
public final boolean isPixelSequential()
```

Returns whether or not the SampleModel represented by the RasterFormatTag is PixelSequential. Note that RasterFormatTag's that indicate data should be copied out of the Raster by the RasterAccessor will always return true for isPixelSequential(). RasterFormatTags that indicate no copying is needed will only return true, if 1) The SampleModel is a ComponentSampleModel. 2) The pixelStride is equal to the number of bands. 3) All the bankIndices[] are equal. 4) All the bandOffsets[] values are less than pixelStride 5) No two bandOffset values are equal.

## getFormatTagID

```
public final int getFormatTagID()
```

Returns the FormatTagID used to construct this RasterFormatTag. Valid values are defined in javax.media.jai.RasterAccessor.

## getBankIndices

```
public final int[] getBankIndices()
```

Returns the bankIndices for the Raster if isPixelSequential() is true. Returns null otherwise. In the COPIED case, the bankIndices will all be 0.

## getNumBands

```
public final int getNumBands()
```

Returns the number of bands in the underlying Raster

## getBandOffsets

```
public final int[] getBandOffsets()
```

Returns the bandOffsets for the Raster if isPixelSequential() is true. Returns null otherwise. In the COPIED case, bankIndices will be numBands sequential integers starting with 0.

## getPixelStride

```
public final int getPixelStride()
```

Returns the pixelStride of the underlying Raster

## javax.media.jai Class RemoteImage

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|
+-- javax.media.jai.RemoteImage
```

---

public class **RemoteImage**

extends PlanarImage

A sub-class of PlanarImage which represents an image on a remote server machine.

The image may be constructed from a RenderedImage or from an imaging chain in either the rendered or renderable mode.

Network errors (detected via throws of RemoteExceptions) are dealt with through retries; when the limit of retries is exceeded, a null Raster may be returned.

Note that the registry of the server will be used. In particular if an OperationRegistry was present in the RenderingHints used to construct a RenderedOp or RenderableOp it will not be serialized and transmitted to the server. Image layout attributes, once requested, are cached locally for speed.

---

### Field Detail

#### DEFAULT\_TIMEOUT

static final int **DEFAULT\_TIMEOUT**

The amount of time to wait between retries.

---

#### DEFAULT\_NUM\_RETRIES

static final int **DEFAULT\_NUM\_RETRIES**

The default number of retries.

---

#### VAR\_MIN\_X

static final int **VAR\_MIN\_X**

Index of local variable.

---

#### VAR\_MIN\_Y

static final int **VAR\_MIN\_Y**

Index of local variable.

---

#### VAR\_WIDTH

static final int **VAR\_WIDTH**

Index of local variable.

---

#### VAR\_HEIGHT

static final int **VAR\_HEIGHT**

Index of local variable.

---

#### VAR\_TILE\_WIDTH

static final int **VAR\_TILE\_WIDTH**

Index of local variable.

---

## **VAR\_TILE\_HEIGHT**

static final int **VAR\_TILE\_HEIGHT**  
Index of local variable.

---

## **VAR\_TILE\_GRID\_X\_OFFSET**

static final int **VAR\_TILE\_GRID\_X\_OFFSET**  
Index of local variable.

---

## **VAR\_TILE\_GRID\_Y\_OFFSET**

static final int **VAR\_TILE\_GRID\_Y\_OFFSET**  
Index of local variable.

---

## **VAR\_SAMPLE\_MODEL**

static final int **VAR\_SAMPLE\_MODEL**  
Index of local variable.

---

## **VAR\_COLOR\_MODEL**

static final int **VAR\_COLOR\_MODEL**  
Index of local variable.

---

## **VAR\_SOURCES**

static final int **VAR\_SOURCES**  
Index of local variable.

---

## **NUM\_VARS**

static final int **NUM\_VARS**  
Index of local variable.

---

## **NULL\_PROPERTY\_CLASS**

private static final java.lang.Class **NULL\_PROPERTY\_CLASS**

---

## **remoteImage**

protected com.sun.media.jai.rmi.RMIImage **remoteImage**  
The RMIImage our data will come from.

---

## **id**

private java.lang.Long **id**

---

## **fieldValid**

protected boolean[] **fieldValid**  
Valid bits for locally cached variables.

---

## **propertyNames**

protected java.lang.String[] **propertyNames**  
Locally cached version of properties.

---

## timeout

protected int **timeout**

The amount of time between retries (milliseconds).

---

## numRetries

protected int **numRetries**

The number of retries.

---

## imageBounds

private java.awt.Rectangle **imageBounds**

## Constructor Detail

### RemoteImage

```
public RemoteImage(java.lang.String serverName,  
                   java.awt.image.RenderedImage source)
```

Constructs a RemoteImage from a RenderedImage.

The RenderedImage source should ideally be a lightweight reference to an image available locally on the server or over a further network link.

Although it is legal to use any RenderedImage, one should be aware that this will require copying of the image data via transmission over a network link.

The name of the server must be supplied in the form appropriate to the implementation. In the reference port of JAI, RMI is used to implement remote imaging so that the server name must be supplied in the format

host:port

where the port number is optional and may be supplied only if the host name is supplied. If this parameter is null the default is to search for the RMImage service on the local host at the default *rmiregistry* port (1099).

**Parameters:**

serverName - The name of the server in the appropriate format.

source - A RenderedImage source which must not be null.

**Throws:**

java.lang.IllegalArgumentException - if source is null.

---

### RemoteImage

```
public RemoteImage(java.lang.String serverName,  
                   RenderedOp source)
```

Constructs a RemoteImage from a RenderedOp, i.e., an imaging directed acyclic graph (DAG).

This DAG will be copied over to the server where it will be transformed into an OpImage chain using the server's local OperationRegistry and available RenderedImageFactory objects.

The name of the server must be supplied in the form appropriate to the implementation. In the reference port of JAI, RMI is used to implement remote imaging so that the server name must be supplied in the format

host:port

where the port number is optional and may be supplied only if the host name is supplied. If this parameter is null the default is to search for the RMImage service on the local host at the default *rmiregistry* port (1099).

Note that the properties of the RemoteImage will be those of the RenderedOp node and not of its rendering.

**Parameters:**

serverName - The name of the server in the appropriate format.

source - A RenderedOp source which must not be null.

**Throws:**

java.lang.IllegalArgumentException - if source is null.

---

### RemoteImage

```
public RemoteImage(java.lang.String serverName,  
                   RenderableOp source,  
                   java.awt.image.renderable.RenderContext renderContext)
```

Constructs a RemoteImage from a RenderableOp and RenderContext. The entire RenderableOp DAG will be copied over to the server.

The name of the server must be supplied in the form appropriate to the implementation. In the reference port of JAI, RMI is used to implement remote imaging so that the server name must be supplied in the format

host:port

where the port number is optional and may be supplied only if the host name is supplied. If this parameter is null the default is to search for the RMIImage service on the local host at the default *rmiregistry* port (1099).

Note that the properties of the RemoteImage will be those of the RenderableOp node and not of its rendering.

**Parameters:**

serverName - The name of the server in the appropriate format.

source - A RenderableOp source which must not be null.

renderContext - The rendering context which may be null.

**Throws:**

java.lang.IllegalArgumentException - if source is null.

## Method Detail

### getRMIImage

```
private void getRMIImage(java.lang.String serverName)
```

Construct an RMIImage on the indicated server.

The name of the server must be supplied in the form

host:port

where the port number is optional and may be supplied only if the host name is supplied. If this parameter is null the default is to search for the RMIImage service on the local host at the default *rmiregistry* port (1099).

The result is cached in the instance variable "remoteImage".

**Parameters:**

serverName - The name of the server in the format described.

### getRMIID

```
private void getRMIID()
```

Get the unique ID to be used to refer to this object on the server. The result is cached in the instance variable "id".

### setRMIProperties

```
private void setRMIProperties(java.lang.String serverName)
```

Cache the argument and the RMI ID as local properties. This is a gross hack to permit chaining of remote images.

**Parameters:**

serverName - The server name as described in the constructors.

### finalize

```
protected void finalize()
```

**Overrides:**

finalize in class PlanarImage

### setTimeout

```
public void setTimeout(int timeout)
```

Set the amount of time between retries.

**Parameters:**

timeout - The time interval between retries (milliseconds). If this is non-positive the time interval is not changed.

### getTimeout

```
public int getTimeout()
```

Gets the amount of time between retries.

### setNumRetries

public void **setNumRetries**(int numRetries)

Set the number of retries.

**Parameters:**

numRetries - The number of retries. If this is non-positive the number of retries is not changed.

---

### getNumRetries

public int **getNumRetries**()

Gets the number of retries.

---

### requestField

protected void **requestField**(int fieldIndex,  
int retries,  
int timeout)

Cause an instance variable of the remote object to be cached locally, retrying a given number of times with a given timeout.

**Parameters:**

fieldIndex - the index of the desired field.

retries - the maximum number of retries; must be positive.

timeout - the timeout interval between retries, in milliseconds; must be positive.

**Throws:**

ArrayIndexOutOfBoundsException - if fieldIndex is negative or >= NUM\_VARS.

IllegalArgumentException - if retries or timeout is non-positive.

---

### requestField

protected void **requestField**(int fieldIndex)

Causes an instance variable of the remote object to be cached locally, retrying indefinitely with a default timeout of 1 second.

**Parameters:**

fieldIndex - the index of the desired field.

**Throws:**

ArrayIndexOutOfBoundsException - if fieldIndex is negative or >= NUM\_VARS.

---

### getMinX

public int **getMinX**()

Returns the X coordinate of the leftmost column of the image.

**Overrides:**

getMinX in class PlanarImage

---

### getMaxX

public int **getMaxX**()

Returns the X coordinate of the column immediately to the right of the rightmost column of the image.

**Overrides:**

getMaxX in class PlanarImage

---

### getMinY

public int **getMinY**()

Returns the Y coordinate of the uppermost row of the image.

**Overrides:**

getMinY in class PlanarImage

---

### getMaxY

public int **getMaxY**()

Returns the Y coordinate of the row immediately below the bottom row of the image.

**Overrides:**

getMaxY in class PlanarImage

---

## getWidth

public int **getWidth()**  
Returns the width of the RemoteImage in pixels.  
**Overrides:**  
getWidth in class PlanarImage

---

## getHeight

public int **getHeight()**  
Returns the height of the RemoteImage in pixels.  
**Overrides:**  
getHeight in class PlanarImage

---

## getTileWidth

public int **getTileWidth()**  
Returns the width of a tile in pixels.  
**Overrides:**  
getTileWidth in class PlanarImage

---

## getTileHeight

public int **getTileHeight()**  
Returns the height of a tile in pixels.  
**Overrides:**  
getTileHeight in class PlanarImage

---

## getTileGridXOffset

public int **getTileGridXOffset()**  
Returns the X offset of the tile grid.  
**Overrides:**  
getTileGridXOffset in class PlanarImage

---

## getTileGridYOffset

public int **getTileGridYOffset()**  
Returns the Y offset of the tile grid.  
**Overrides:**  
getTileGridYOffset in class PlanarImage

---

## getSampleModel

public java.awt.image.SampleModel **getSampleModel()**  
Returns the SampleModel associated with this image.  
**Overrides:**  
getSampleModel in class PlanarImage

---

## getColorModel

public java.awt.image.ColorModel **getColorModel()**  
Returns the ColorModel associated with this image.  
**Overrides:**  
getColorModel in class PlanarImage

---

## getSources

```
public java.util.Vector getSources()
```

Returns a vector of RenderedImages that are the sources of image data for this RenderedImage. Note that this method will often return null.

**Overrides:**

getSources in class PlanarImage

---

## getProperty

```
public java.lang.Object getProperty(java.lang.String name)
```

Gets a property from the property set of this image. If the property name is not recognized, java.awt.Image.UndefinedProperty will be returned.

**Parameters:**

name - the name of the property to get, as a String.

**Returns:**

a reference to the property Object, or the value java.awt.Image.UndefinedProperty.

**Overrides:**

getProperty in class PlanarImage

---

## getPropertyNames

```
public java.lang.String[] getPropertyNames()
```

Returns a list of names recognized by getProperty.

**Overrides:**

getPropertyNames in class PlanarImage

---

## getTile

```
public java.awt.image.Raster getTile(int x,  
                                     int y)
```

Returns tile (x, y). Note that x and y are indexes into the tile array not pixel locations. The Raster that is returned is a copy.

**Parameters:**

x - the X index of the requested tile in the tile array

y - the Y index of the requested tile in the tile array

**Overrides:**

getTile in class PlanarImage

---

## getData

```
public java.awt.image.Raster getData()
```

Returns the image as one large tile.

**Overrides:**

getData in class PlanarImage

---

## getData

```
public java.awt.image.Raster getData(java.awt.Rectangle rect)
```

Returns an arbitrary rectangular region of the RemoteImage.

The rect parameter may be null, in which case the entire image data is returned in the Raster.

If rect is non-null but does not intersect the image bounds at all, an IllegalArgumentException will be thrown.

**Overrides:**

getData in class PlanarImage

---

## copyData

```
public java.awt.image.WritableRaster copyData(java.awt.image.WritableRaster raster)
```

Returns an arbitrary rectangular region of the RemoteImage in a user-supplied WritableRaster. The rectangular region is the entire image if the argument is null or the intersection of the argument bounds with the image bounds if the region is non-null. If the argument is non-null but has bounds which have an empty intersection with the image bounds the return value will be null. The return value may also be null if the argument is non-null but is incompatible with the Raster returned from the remote image.

**Overrides:**

copyData in class PlanarImage

---

## javax.media.jai Class RenderableGraphics

```
java.lang.Object
|
+-- java.awt.Graphics
|   |
|   +-- java.awt.Graphics2D
|       |
|       +-- javax.media.jai.RenderableGraphics
```

---

public class **RenderableGraphics**  
extends java.awt.Graphics2D  
implements java.awt.image.renderable.RenderableImage

An implementation of Graphics2D with RenderableImage semantics. In other words, content may be drawn into the image using the Graphics2D interface and later be turned into RenderedImages with different resolutions and characteristics.

A RenderableGraphics occupies a region of the plane specified at the time of construction.

The contents of RenderableImages that are drawn onto a RenderableGraphics are accessed only at the time of rendering, not the time of drawing.

Since the methods of this class all derive from Graphics2D and RenderableImage, they are not all commented individually.

## Constructor Detail

### RenderableGraphics

```
public RenderableGraphics(java.awt.geom.Rectangle2D dimensions)
```

Constructs a RenderableGraphics given a bounding Rectangle2D.

**Parameters:**

dimensions - The bounding Rectangle2D.

### RenderableGraphics

```
private RenderableGraphics(java.awt.geom.Rectangle2D dimensions,  
                           java.util.LinkedList opArgList,  
                           java.awt.Point origin,  
                           java.awt.Graphics2D g)
```

Constructs a RenderableGraphics given a bounding Rectangle2D, an origin, and a Graphics2D object from which to initialize the RenderableGraphics state. The Graphics2D may be null.

**Parameters:**

dimensions - The bounding Rectangle2D.

opArgList - The list of operations and arguments.

dimensions - The origin.

dimensions - The Graphics2D state source; may be null.

## Method Detail

### getBogusGraphics2D

```
private java.awt.Graphics2D getBogusGraphics2D()
```

Creates a bogus Graphics2D object to be used to retrieve information dependent on system aspects which are image-independent.

The dispose( ) method of the Graphics2D object returned should be called to free the associated resources as\ soon as possible.

**Returns:**

A Graphics2D object.

## createTiledImage

```
private TiledImage createTiledImage(java.awt.RenderingHints hints,  
                                     java.awt.Rectangle bounds)
```

Create a TiledImage to be used as the canvas.

**Parameters:**

hints - RenderingHints from which to derive an ImageLayout.

bounds - The bounding box of the TiledImage.

**Returns:**

A TiledImage.

---

## queueOpArg

```
private void queueOpArg(java.lang.String name,  
                        java.lang.Class[] argTypes,  
                        java.lang.Object[] args)
```

Queue a Graphics2D operation and its argument list in the linked list of operations and arguments. The name of the operation and the array of class types of its arguments are used to determine the associated Method object. The Method object and array of Object arguments are appended to the list as an ordered pair of the form (Method, Object[]).

**Parameters:**

name - The name of the Graphics2D operation.

argTypes - An array of the Classes of the arguments of the specified operation.

args - The arguments of the operation as an array of Objects.

---

## evaluateOpList

```
private void evaluateOpList(java.awt.Graphics2D g2d)
```

Evaluate the queue of Graphics2D operations on the specified Graphics2D object.

**Parameters:**

g2d - The Graphics2D on which to evaluate the operation queue.

---

## create

```
public java.awt.Graphics create()
```

**Overrides:**

create in class java.awt.Graphics

---

## getColor

```
public java.awt.Color getColor()
```

**Overrides:**

getColor in class java.awt.Graphics

---

## setColor

```
public void setColor(java.awt.Color c)
```

**Overrides:**

setColor in class java.awt.Graphics

---

## setPaintMode

```
public void setPaintMode()
```

**Overrides:**

setPaintMode in class java.awt.Graphics

---

## setXORMode

```
public void setXORMode(java.awt.Color c1)
```

**Overrides:**

setXORMode in class java.awt.Graphics

---

## getFont

public java.awt.Font **getFont**()

### Overrides:

getFont in class java.awt.Graphics

---

## setFont

public void **setFont**(java.awt.Font font)

### Overrides:

setFont in class java.awt.Graphics

---

## getFontMetrics

public java.awt.FontMetrics **getFontMetrics**(java.awt.Font f)

### Overrides:

getFontMetrics in class java.awt.Graphics

---

## getClipBounds

public java.awt.Rectangle **getClipBounds**()

### Overrides:

getClipBounds in class java.awt.Graphics

---

## clipRect

```
public void clipRect(int x,  
                    int y,  
                    int width,  
                    int height)
```

### Overrides:

clipRect in class java.awt.Graphics

---

## setClip

```
public void setClip(int x,  
                  int y,  
                  int width,  
                  int height)
```

### Overrides:

setClip in class java.awt.Graphics

---

## getClip

public java.awt.Shape **getClip**()

### Overrides:

getClip in class java.awt.Graphics

---

## setClip

public void **setClip**(java.awt.Shape clip)

### Overrides:

setClip in class java.awt.Graphics

---

## copyArea

```
public void copyArea(int x,  
                   int y,  
                   int width,  
                   int height,  
                   int dx,  
                   int dy)
```

**Overrides:**  
copyArea in class java.awt.Graphics

---

## **drawLine**

```
public void drawLine(int x1,  
                     int y1,  
                     int x2,  
                     int y2)
```

**Overrides:**  
drawLine in class java.awt.Graphics

---

## **fillRect**

```
public void fillRect(int x,  
                    int y,  
                    int width,  
                    int height)
```

**Overrides:**  
fillRect in class java.awt.Graphics

---

## **clearRect**

```
public void clearRect(int x,  
                     int y,  
                     int width,  
                     int height)
```

**Overrides:**  
clearRect in class java.awt.Graphics

---

## **drawRoundRect**

```
public void drawRoundRect(int x,  
                          int y,  
                          int width,  
                          int height,  
                          int arcWidth,  
                          int arcHeight)
```

**Overrides:**  
drawRoundRect in class java.awt.Graphics

---

## **fillRoundRect**

```
public void fillRoundRect(int x,  
                          int y,  
                          int width,  
                          int height,  
                          int arcWidth,  
                          int arcHeight)
```

**Overrides:**  
fillRoundRect in class java.awt.Graphics

---

## **draw3DRect**

```
public void draw3DRect(int x,  
                      int y,  
                      int width,  
                      int height,  
                      boolean raised)
```

**Overrides:**  
draw3DRect in class java.awt.Graphics2D

---

## fill3DRect

```
public void fill3DRect(int x,  
                      int y,  
                      int width,  
                      int height,  
                      boolean raised)
```

### Overrides:

fill3DRect in class java.awt.Graphics2D

---

## drawOval

```
public void drawOval(int x,  
                    int y,  
                    int width,  
                    int height)
```

### Overrides:

drawOval in class java.awt.Graphics

---

## fillOval

```
public void fillOval(int x,  
                    int y,  
                    int width,  
                    int height)
```

### Overrides:

fillOval in class java.awt.Graphics

---

## drawArc

```
public void drawArc(int x,  
                   int y,  
                   int width,  
                   int height,  
                   int startAngle,  
                   int arcAngle)
```

### Overrides:

drawArc in class java.awt.Graphics

---

## fillArc

```
public void fillArc(int x,  
                   int y,  
                   int width,  
                   int height,  
                   int startAngle,  
                   int arcAngle)
```

### Overrides:

fillArc in class java.awt.Graphics

---

## drawPolyline

```
public void drawPolyline(int[] xPoints,  
                        int[] yPoints,  
                        int nPoints)
```

### Overrides:

drawPolyline in class java.awt.Graphics

---

## drawPolygon

```
public void drawPolygon(int[] xPoints,  
                      int[] yPoints,  
                      int nPoints)
```

**Overrides:**  
drawPolygon in class java.awt.Graphics

---

## fillPolygon

```
public void fillPolygon(int[] xPoints,  
                        int[] yPoints,  
                        int nPoints)
```

**Overrides:**  
fillPolygon in class java.awt.Graphics

---

## drawString

```
public void drawString(java.lang.String str,  
                       int x,  
                       int y)
```

**Overrides:**  
drawString in class java.awt.Graphics2D

---

## drawImage

```
public boolean drawImage(java.awt.Image img,  
                         int x,  
                         int y,  
                         java.awt.image.ImageObserver observer)
```

**Overrides:**  
drawImage in class java.awt.Graphics

---

## drawImage

```
public boolean drawImage(java.awt.Image img,  
                         int x,  
                         int y,  
                         int width,  
                         int height,  
                         java.awt.image.ImageObserver observer)
```

**Overrides:**  
drawImage in class java.awt.Graphics

---

## drawImage

```
public boolean drawImage(java.awt.Image img,  
                         int x,  
                         int y,  
                         java.awt.Color bgcolor,  
                         java.awt.image.ImageObserver observer)
```

**Overrides:**  
drawImage in class java.awt.Graphics

---

## drawImage

```
public boolean drawImage(java.awt.Image img,  
                         int x,  
                         int y,  
                         int width,  
                         int height,  
                         java.awt.Color bgcolor,  
                         java.awt.image.ImageObserver observer)
```

**Overrides:**  
drawImage in class java.awt.Graphics

---

## drawImage

```
public boolean drawImage(java.awt.Image img,  
                        int dx1,  
                        int dy1,  
                        int dx2,  
                        int dy2,  
                        int sx1,  
                        int sy1,  
                        int sx2,  
                        int sy2,  
                        java.awt.image.ImageObserver observer)
```

### Overrides:

drawImage in class java.awt.Graphics

---

## drawImage

```
public boolean drawImage(java.awt.Image img,  
                        int dx1,  
                        int dy1,  
                        int dx2,  
                        int dy2,  
                        int sx1,  
                        int sy1,  
                        int sx2,  
                        int sy2,  
                        java.awt.Color bgcolor,  
                        java.awt.image.ImageObserver observer)
```

### Overrides:

drawImage in class java.awt.Graphics

---

## dispose

```
public void dispose()
```

### Overrides:

dispose in class java.awt.Graphics

---

## addRenderingHints

```
public void addRenderingHints(java.util.Map hints)
```

### Overrides:

addRenderingHints in class java.awt.Graphics2D

---

## draw

```
public void draw(java.awt.Shape s)
```

### Overrides:

draw in class java.awt.Graphics2D

---

## drawImage

```
public boolean drawImage(java.awt.Image img,  
                        java.awt.geom.AffineTransform xform,  
                        java.awt.image.ImageObserver obs)
```

### Overrides:

drawImage in class java.awt.Graphics2D

---

## drawRenderedImage

```
public void drawRenderedImage(java.awt.image.RenderedImage img,  
                        java.awt.geom.AffineTransform xform)
```

### Overrides:

drawRenderedImage in class java.awt.Graphics2D

---

## drawRenderableImage

```
public void drawRenderableImage(java.awt.image.renderable.RenderableImage img,  
                                java.awt.geom.AffineTransform xform)
```

### Overrides:

drawRenderableImage in class java.awt.Graphics2D

---

## drawImage

```
public void drawImage(java.awt.image.BufferedImage img,  
                      java.awt.image.BufferedImageOp op,  
                      int x,  
                      int y)
```

### Overrides:

drawImage in class java.awt.Graphics2D

---

## drawString

```
public void drawString(java.lang.String s,  
                       float x,  
                       float y)
```

### Overrides:

drawString in class java.awt.Graphics2D

---

## drawString

```
public void drawString(java.text.AttributedString iterator,  
                       int x,  
                       int y)
```

### Overrides:

drawString in class java.awt.Graphics2D

---

## drawString

```
public void drawString(java.text.AttributedString iterator,  
                       float x,  
                       float y)
```

### Overrides:

drawString in class java.awt.Graphics2D

---

## drawGlyphVector

```
public void drawGlyphVector(java.awt.font.GlyphVector v,  
                             float x,  
                             float y)
```

### Overrides:

drawGlyphVector in class java.awt.Graphics2D

---

## fill

```
public void fill(java.awt.Shape s)
```

### Overrides:

fill in class java.awt.Graphics2D

---

## hit

```
public boolean hit(java.awt.Rectangle rect,  
                  java.awt.Shape s,  
                  boolean onStroke)
```

### Overrides:

hit in class java.awt.Graphics2D

---

## getDeviceConfiguration

public java.awt.GraphicsConfiguration **getDeviceConfiguration**()

### Overrides:

getDeviceConfiguration in class java.awt.Graphics2D

---

## getFontRenderContext

public java.awt.font.FontRenderContext **getFontRenderContext**()

### Overrides:

getFontRenderContext in class java.awt.Graphics2D

---

## setComposite

public void **setComposite**(java.awt.Composite comp)

### Overrides:

setComposite in class java.awt.Graphics2D

---

## setPaint

public void **setPaint**(java.awt.Paint paint)

### Overrides:

setPaint in class java.awt.Graphics2D

---

## setStroke

public void **setStroke**(java.awt.Stroke s)

### Overrides:

setStroke in class java.awt.Graphics2D

---

## setRenderingHint

public void **setRenderingHint**(java.awt.RenderingHints.Key hintKey,  
java.lang.Object hintValue)

### Overrides:

setRenderingHint in class java.awt.Graphics2D

---

## getRenderingHint

public java.lang.Object **getRenderingHint**(java.awt.RenderingHints.Key hintKey)

### Overrides:

getRenderingHint in class java.awt.Graphics2D

---

## setRenderingHints

public void **setRenderingHints**(java.util.Map hints)

### Overrides:

setRenderingHints in class java.awt.Graphics2D

---

## getRenderingHints

public java.awt.RenderingHints **getRenderingHints**()

### Overrides:

getRenderingHints in class java.awt.Graphics2D

---

## **translate**

```
public void translate(int x,  
                     int y)
```

### **Overrides:**

translate in class java.awt.Graphics2D

---

## **translate**

```
public void translate(double x,  
                     double y)
```

### **Overrides:**

translate in class java.awt.Graphics2D

---

## **rotate**

```
public void rotate(double theta)
```

### **Overrides:**

rotate in class java.awt.Graphics2D

---

## **rotate**

```
public void rotate(double theta,  
                  double x,  
                  double y)
```

### **Overrides:**

rotate in class java.awt.Graphics2D

---

## **scale**

```
public void scale(double sx,  
                 double sy)
```

### **Overrides:**

scale in class java.awt.Graphics2D

---

## **shear**

```
public void shear(double shx,  
                 double shy)
```

### **Overrides:**

shear in class java.awt.Graphics2D

---

## **transform**

```
public void transform(java.awt.geom.AffineTransform Tx)
```

### **Overrides:**

transform in class java.awt.Graphics2D

---

## **setTransform**

```
public void setTransform(java.awt.geom.AffineTransform Tx)
```

### **Overrides:**

setTransform in class java.awt.Graphics2D

---

## **getTransform**

```
public java.awt.geom.AffineTransform getTransform()
```

### **Overrides:**

getTransform in class java.awt.Graphics2D

---

## getPaint

public java.awt.Paint **getPaint**()

### Overrides:

getPaint in class java.awt.Graphics2D

---

## getComposite

public java.awt.Composite **getComposite**()

### Overrides:

getComposite in class java.awt.Graphics2D

---

## setBackground

public void **setBackground**(java.awt.Color color)

### Overrides:

setBackground in class java.awt.Graphics2D

---

## getBackground

public java.awt.Color **getBackground**()

### Overrides:

getBackground in class java.awt.Graphics2D

---

## getStroke

public java.awt.Stroke **getStroke**()

### Overrides:

getStroke in class java.awt.Graphics2D

---

## clip

public void **clip**(java.awt.Shape s)

### Overrides:

clip in class java.awt.Graphics2D

---

## getSources

public java.util.Vector **getSources**()

### Specified by:

getSources in interface java.awt.image.renderable.RenderableImage

---

## getProperty

public java.lang.Object **getProperty**(java.lang.String name)

### Specified by:

getProperty in interface java.awt.image.renderable.RenderableImage

---

## getPropertyNames

public java.lang.String[] **getPropertyNames**()

### Specified by:

getPropertyNames in interface java.awt.image.renderable.RenderableImage

---

## isDynamic

public boolean **isDynamic**()

### Specified by:

isDynamic in interface java.awt.image.renderable.RenderableImage

---

## getWidth

public float **getWidth()**

**Specified by:**

getWidth in interface java.awt.image.renderable.RenderableImage

---

## getHeight

public float **getHeight()**

**Specified by:**

getHeight in interface java.awt.image.renderable.RenderableImage

---

## getMinX

public float **getMinX()**

**Specified by:**

getMinX in interface java.awt.image.renderable.RenderableImage

---

## getMinY

public float **getMinY()**

**Specified by:**

getMinY in interface java.awt.image.renderable.RenderableImage

---

## createScaledRendering

```
public java.awt.image.RenderedImage createScaledRendering(int w,  
                                                         int h,  
                                                         java.awt.RenderingHints hints)
```

**Specified by:**

createScaledRendering in interface java.awt.image.renderable.RenderableImage

---

## createDefaultRendering

```
public java.awt.image.RenderedImage createDefaultRendering()
```

**Specified by:**

createDefaultRendering in interface java.awt.image.renderable.RenderableImage

---

## createRendering

```
public java.awt.image.RenderedImage createRendering(java.awt.image.renderable.RenderContext renderContext)
```

Creates a `RenderedImage` that represents a rendering of this image using a given `RenderContext`. This is the most general way to obtain a rendering of a `RenderableImage`.

The created `RenderedImage` may have a property identified by the String `HINTS_OBSERVED` to indicate which `RenderingHints` (from the `RenderContext`) were used to create the image. In addition any `RenderedImages` that are obtained via the `getSources()` method on the created `RenderedImage` may have such a property.

The bounds of the `RenderedImage` are determined from the `dimensions` parameter passed to the `RenderableGraphics` constructor. These bounds will be transformed by any `AffineTransform` from the `RenderContext`. The `RenderingHints` from the `RenderContext` may be used to specify the tile width and height, `SampleModel`, and `ColorModel` by supplying an `ImageLayout` hint. The precedence for determining tile width and height is to use firstly values provided explicitly via the `ImageLayout`, secondly the width and height of the `SampleModel` in the hint, and thirdly the bounds of the `RenderableGraphics` object after transformation.

If either the `SampleModel` or `ColorModel` is null, an attempt will be made to derive a compatible value for the null object from the non-null object. If they are both null, a 3-band byte `TiledImage` with a null `ColorModel` and a `PixelInterleavedSampleModel` will be created.

**Specified by:**

createRendering in interface java.awt.image.renderable.RenderableImage

**Parameters:**

`renderContext` - the `RenderContext` to use to produce the rendering.

**Returns:**

a `RenderedImage` containing the rendered data.

---

## javax.media.jai Class RenderableImageAdapter

```
java.lang.Object
|
+-- javax.media.jai.RenderableImageAdapter
```

---

public final class **RenderableImageAdapter**  
extends java.lang.Object  
implements java.awt.image.renderable.RenderableImage, PropertySource

An adapter class for externally-generated RenderableImages. All methods are simply forwarded to the image being adapted. The purpose of this class is simply to ensure that the PropertySource interface is available for all JAI images.

---

### Field Detail

#### im

private java.awt.image.renderable.RenderableImage **im**  
A reference to the external RenderableImage.

---

### Constructor Detail

#### RenderableImageAdapter

public **RenderableImageAdapter**( java.awt.image.renderable.RenderableImage im)  
Constructs a RenderableImageAdapter from a RenderableImage.  
**Throws:**  
NullPointerException - if im is null.

---

### Method Detail

#### wrapRenderableImage

public static RenderableImageAdapter **wrapRenderableImage**( java.awt.image.renderable.RenderableImage im)  
Adapts a RenderableImage into a RenderableImageAdapter. If the image is already an instance of RenderableImageAdapter, it is returned unchanged.  
**Parameters:**  
im - a RenderableImage.  
**Returns:**  
a RenderableImageAdapter.  
**Throws:**  
NullPointerException - if im is null.

---

#### getSources

public final java.util.Vector **getSources**()  
**Specified by:**  
getSources in interface java.awt.image.renderable.RenderableImage

---

#### getProperty

public final java.lang.Object **getProperty**(java.lang.String name)  
Gets a property from the property set of this image. If the property name is not recognized, java.awt.Image.UndefinedProperty will be returned.  
**Specified by:**  
getProperty in interface java.awt.image.renderable.RenderableImage  
**Parameters:**  
name - the name of the property to get, as a String.  
**Returns:**  
a reference to the property Object, or the value java.awt.Image.UndefinedProperty.

**Throws:**  
java.lang.IllegalArgumentException - if name is null.

---

## getPropertyNames

public final java.lang.String[] **getPropertyNames**()  
Returns a list of the properties recognized by this image. If no properties are available, null will be returned.  
**Specified by:**  
getPropertyNames in interface java.awt.image.renderable.RenderableImage  
**Returns:**  
an array of Strings representing valid property names.

---

## getPropertyNames

public java.lang.String[] **getPropertyNames**(java.lang.String prefix)  
Returns an array of Strings recognized as names by this property source that begin with the supplied prefix. If no property names match, null will be returned. The comparison is done in a case-independent manner.  
**Specified by:**  
getPropertyNames in interface PropertySource  
**Returns:**  
an array of Strings giving the valid property names.  
**Throws:**  
NullPointerException - if prefix is null.

---

## getWidth

public final float **getWidth**()  
Gets the width in user coordinate space. By convention, the usual width of a RenderableImage is equal to the image's aspect ratio (width divided by height).  
**Specified by:**  
getWidth in interface java.awt.image.renderable.RenderableImage  
**Returns:**  
the width of the image in user coordinates.

---

## getHeight

public final float **getHeight**()  
Gets the height in user coordinate space. By convention, the usual height of a RenderedImage is equal to 1.0F.  
**Specified by:**  
getHeight in interface java.awt.image.renderable.RenderableImage  
**Returns:**  
the height of the image in user coordinates.

---

## getMinX

public final float **getMinX**()  
Gets the minimum X coordinate of the rendering-independent image.  
**Specified by:**  
getMinX in interface java.awt.image.renderable.RenderableImage

---

## getMinY

public final float **getMinY**()  
Gets the minimum Y coordinate of the rendering-independent image.  
**Specified by:**  
getMinY in interface java.awt.image.renderable.RenderableImage

---

## isDynamic

public final boolean **isDynamic**()

Returns true if successive renderings (that is, calls to `createRendering()` or `createScaledRendering()`) with the same arguments may produce different results. This method may be used to determine whether an existing rendering may be cached and reused.

**Specified by:**

`isDynamic` in interface `java.awt.image.renderable.RenderableImage`

---

## createScaledRendering

public final `java.awt.image.RenderedImage` **createScaledRendering**(int w,  
int h,  
`java.awt.RenderingHints` hints)

Gets a `RenderedImage` instance of this image with width `w`, and height `h` in pixels. The `RenderContext` is built automatically with an appropriate `usr2dev` transform and an area of interest of the full image. All the rendering hints come from hints passed in.

**Specified by:**

`createScaledRendering` in interface `java.awt.image.renderable.RenderableImage`

**Parameters:**

`w` - the width of rendered image in pixels.  
`h` - the height of rendered image in pixels.  
`hints` - a `RenderingHints` object containing rendering hints.

**Returns:**

a `RenderedImage` containing the rendered data.

---

## createDefaultRendering

public final `java.awt.image.RenderedImage` **createDefaultRendering**()

Gets a `RenderedImage` instance of this image with a default width and height in pixels. The `RenderContext` is built automatically with an appropriate `usr2dev` transform and an area of interest of the full image. All the rendering hints come from hints passed in. Implementors of this interface must be sure that there is a defined default width and height.

**Specified by:**

`createDefaultRendering` in interface `java.awt.image.renderable.RenderableImage`

**Returns:**

a `RenderedImage` containing the rendered data.

---

## createRendering

public final `java.awt.image.RenderedImage` **createRendering**(`java.awt.image.renderable.RenderContext` renderContext)

Gets a `RenderedImage` instance of this image from a `RenderContext`. This is the most general way to obtain a rendering of a `RenderableImage`.

**Specified by:**

`createRendering` in interface `java.awt.image.renderable.RenderableImage`

**Parameters:**

`renderContext` - the `RenderContext` to use to produce the rendering.

**Returns:**

a `RenderedImage` containing the rendered data.

---

## javax.media.jai Class RenderableOp

```
java.lang.Object
|
+-- javax.media.jai.RenderableOp
```

---

public class **RenderableOp**  
extends java.lang.Object  
implements PropertySource, java.awt.image.renderable.RenderableImage, java.io.Serializable  
A JAI version of RenderableImageOp. Instead of taking a ContextualRenderedImageFactory directly, we make use of the operation registry.

### See Also:

OperationRegistry, ContextualRenderedImageFactory, RenderableImageOp

---

## Field Detail

### theRegistry

```
private transient OperationRegistry theRegistry
    The OperationRegistry that is used to render this node.
```

---

### operationName

```
private java.lang.String operationName
    The name of the operation this node represents.
```

---

### paramBlock

```
private transient java.awt.image.renderable.ParameterBlock paramBlock
    The input arguments for this operation, including sources and/or parameters.
```

---

### thePropertySource

```
protected transient PropertySource thePropertySource
```

---

### boundingBox

```
protected transient java.awt.geom.Rectangle2D boundingBox
```

---

### crif

```
protected transient java.awt.image.renderable.ContextualRenderedImageFactory crif
```

---

### localProperties

```
private transient java.util.Hashtable localProperties
    Locally-stored properties.
```

---

### volatilePropertyInfo

```
private java.util.Vector volatilePropertyInfo
    Cache of information in "thePropertySource" which is lost in the serialization/deserialization process. This includes the PropertyGenerators added via addPropertyGenerator() and the names of properties specified via suppressProperty(). The nature of each Vector element is determined by its class, i.e., String (name of a suppressed property) or PropertyGenerator.
```

## Constructor Detail

## RenderableOp

```
public RenderableOp(OperationRegistry registry,  
                    java.lang.String opName,  
                    java.awt.image.renderable.ParameterBlock pb)
```

Constructs a `RenderableOp` given the name of the operation to be performed and a `ParameterBlock` containing `RenderableImage` sources and other parameters. Any `RenderedImage` sources referenced by the `ParameterBlock` will be ignored.

**Parameters:**

registry - The `OperationRegistry` to be used for instantiation. if null, the default registry is used.

opName - The operation name.

pb - The sources and other parameters. If null, it is assumed that this node has no sources and parameters.

**Throws:**

`NullPointerException` - if opName is null.

---

## RenderableOp

```
public RenderableOp(java.lang.String opName,  
                    java.awt.image.renderable.ParameterBlock pb)
```

Constructs a `RenderableOp` given the name of the operation to be performed and a `ParameterBlock` containing `RenderableImage` sources and other parameters. Any `RenderedImage` sources referenced by the `ParameterBlock` will be ignored.

**Parameters:**

opName - The operation name.

pb - The sources and other parameters. If null, it is assumed that this node has no sources and parameters.

**Throws:**

`NullPointerException` - if opName is null.

---

## Method Detail

### getRegistry

```
public OperationRegistry getRegistry()
```

Returns the `OperationRegistry` that is used by this node. If the registry had not been set, the default registry is returned.

---

### setRegistry

```
public void setRegistry(OperationRegistry registry)
```

Sets the `OperationRegistry` that is used by this node. If the specified registry is null, the default registry is used.

---

### getOperationName

```
public java.lang.String getOperationName()
```

Returns the name of the operation this node represents as a `String`.

---

### setOperationName

```
public void setOperationName(java.lang.String opName)
```

Sets the name of the operation this node represents. The parameter is saved by reference.

**Parameters:**

opName - The new operation name to be set.

**Throws:**

`NullPointerException` - if opName is null.

---

### getParameterBlock

```
public java.awt.image.renderable.ParameterBlock getParameterBlock()
```

Returns the `ParameterBlock` of this node.

---

## setParameterBlock

```
public void setParameterBlock(java.awt.image.renderable.ParameterBlock pb)
```

Sets the ParameterBlock of this node. If the speicified new ParameterBlock is null, it is assumed that this node has no input sources and parameters. The parameter is saved by reference.

This method does not validate the content of the supplied ParameterBlock. The caller should ensure that the sources and parameters in the ParameterBlock are suitable for the operation this node represents; otherwise some form of error or exception may occur at the time of rendering.

**Parameters:**

pb - The new ParameterBlock to be set; it may be null.

---

## getSources

```
public java.util.Vector getSources()
```

Returns a vector of RenderableImages that are the sources of image data for this RenderableImage. Note that this method may return an empty vector, to indicate that the image has sources but none of them is a RenderableImage, or null to indicate the image has no source of any type.

**Specified by:**

getSources in interface java.awt.image.renderable.RenderableImage

**Returns:**

a (possibly empty) Vector of RenderableImages, or null.

---

## getRenderableSources

```
private java.util.Vector getRenderableSources()
```

---

## createPropertySource

```
private void createPropertySource()
```

Creates a PropertySource if none exists.

---

## createVolatilePropertyVector

```
private void createVolatilePropertyVector()
```

Creates a volatile property info Vector if none exists.

---

## createLocalProperties

```
private void createLocalProperties()
```

Initialize the localProperties Hashtable if needed.

---

## getPropertyNames

```
public java.lang.String[] getPropertyNames()
```

Returns the names of properties available from this node. These properties are a combination of those derived from prior nodes in the imaging chain, those set locally, and those generated by the rendering.

**Specified by:**

getPropertyNames in interface PropertySource

**Returns:**

An array of Strings containing valid property names.

---

## getPropertyNames

```
public java.lang.String[] getPropertyNames(java.lang.String prefix)
```

Returns an array of Strings recognized as names by this property source that begin with the supplied prefix. If no property names match, null will be returned. The comparison is done in a case-independent manner.

**Specified by:**

getPropertyNames in interface PropertySource

**Returns:**

an array of Strings giving the valid property names.

---

## getProperty

public java.lang.Object **getProperty**(java.lang.String name)

Gets a property from the property set of this image. If the property name is not recognized, java.awt.Image.UndefinedProperty will be returned.

**Specified by:**

getProperty in interface PropertySource

**Parameters:**

name - the name of the property to get, as a String.

**Returns:**

a reference to the property Object, or the value java.awt.Image.UndefinedProperty.

---

## setProperty

public void **setProperty**(java.lang.String name,  
java.lang.Object value)

Sets a local property on a node. The synthetic properties (containing image width, height, and position) may not be set. Local property settings override properties derived from prior nodes in the imaging chain.

If the node is serialized then serializable properties will also be serialized but non-serializable properties will be lost.

**Parameters:**

name - a String representing the property name.

value - the property's value, as an Object.

---

## isDynamic

public boolean **isDynamic**()

Returns false, i.e., successive renderings with the same arguments will produce identical results.

**Specified by:**

isDynamic in interface java.awt.image.renderable.RenderableImage

---

## addPropertyGenerator

public void **addPropertyGenerator**(PropertyGenerator pg)

Adds a PropertyGenerator to the node. The property values emitted by this property generator override any previous definitions.

**Parameters:**

pg - a PropertyGenerator to be added to this node's property environment.

---

## suppressProperty

public void **suppressProperty**(java.lang.String name)

Removes a named property from the property environment of this node. Subsequent calls to getProperty(name) will return null, and name will not appear on the list of properties emitted by getPropertyNames().

**Parameters:**

name - a String naming the property to be suppressed.

---

## getWidth

public float **getWidth**()

Return the rendering-independent width of the image.

**Specified by:**

getWidth in interface java.awt.image.renderable.RenderableImage

**Returns:**

the image width as a float.

---

## getHeight

public float **getHeight**()

Return the rendering-independent height of the image.

**Specified by:**

getHeight in interface java.awt.image.renderable.RenderableImage

**Returns:**  
the image height as a float.

---

## getMinX

public float **getMinX**()  
Gets the minimum X coordinate of the rendering-independent image data.  
**Specified by:**  
getMinX in interface java.awt.image.renderable.RenderableImage

---

## getMinY

public float **getMinY**()  
Gets the minimum Y coordinate of the rendering-independent image data.  
**Specified by:**  
getMinY in interface java.awt.image.renderable.RenderableImage

---

## createDefaultRendering

public java.awt.image.RenderedImage **createDefaultRendering**()  
Returns a RenderedImage instance of this image equivalent to what would be obtained by invoking createRendering() with the identity transform, an area of interest equal to the image bounds, and no rendering hints.  
This method does not validate sources and parameters supplied in the ParameterBlock against the specification of the operation this node represents. It is the caller's responsibility to ensure that the data in the ParameterBlock are suitable for this operation. Otherwise, some kind of exception or error will occur.  
**Specified by:**  
createDefaultRendering in interface java.awt.image.renderable.RenderableImage  
**Returns:**  
The default RenderedImage.

---

## createScaledRendering

public java.awt.image.RenderedImage **createScaledRendering**(int w,  
int h,  
java.awt.RenderingHints hints)  
Gets a RenderedImage instance of this image with width w, and height h in pixels. The RenderContext is built automatically with an appropriate usr2dev transform and an area of interest of the full image. All the rendering hints come from hints passed in.  
If w == 0, it will be taken to equal Math.round(h\*(getWidth()/getHeight())). Similarly, if h == 0, it will be taken to equal Math.round(w\*(getHeight()/getWidth())). One of w or h must be non-zero or else an IllegalArgumentException will be thrown.  
This method does not validate sources and parameters supplied in the ParameterBlock against the specification of the operation this node represents. It is the caller's responsibility to ensure that the data in the ParameterBlock are suitable for this operation. Otherwise, some kind of exception or error will occur.  
**Specified by:**  
createScaledRendering in interface java.awt.image.renderable.RenderableImage  
**Parameters:**  
w - the width of rendered image in pixels, or 0.  
h - the height of rendered image in pixels, or 0.  
hints - a RenderingHints object containing hints.  
**Returns:**  
a RenderedImage containing the rendered data.  
**Throws:**  
java.lang.IllegalArgumentException - if both w and h are zero.

---

## createRendering

public java.awt.image.RenderedImage **createRendering**(java.awt.image.renderable.RenderContext renderContext)  
Gets a RenderedImage that represented a rendering of this image using a given RenderContext. This is the most general way to obtain a rendering of a RenderableImage.  
This method does not validate sources and parameters supplied in the ParameterBlock against the specification of the operation this node represents. It is the caller's responsibility to ensure that the data in the ParameterBlock are suitable for this operation. Otherwise, some kind of exception or error will occur.

`JAI.createRenderable()` is the method that does the validation. Therefore, it is strongly recommended that all `RenderableOps` are created using `JAI.createRenderable()`.

The `RenderContext` may contain a `Shape` that represents the area-of-interest (aoi). If the aoi is specified, it is still legal to return an image that's larger than this aoi. Therefore, by default, the aoi, if specified, is ignored at the rendering.

**Specified by:**

`createRendering` in interface `java.awt.image.renderable.RenderableImage`

**Parameters:**

`renderContext` - the `RenderContext` to use to produce the rendering.

**Returns:**

a `RenderedImage` containing the rendered data.

---

## **getRenderedImage**

```
private java.awt.image.RenderedImage getRenderedImage(java.awt.image.renderable.RenderContext renderContext)
```

---

## **findCRIF**

```
private java.awt.image.renderable.ContextualRenderedImageFactory findCRIF()
```

Use registry to find an appropriate CRIF

---

## **getSource**

```
public java.lang.Object getSource(int index)
```

Returns one of the node's sources as an `Object`.

**Parameters:**

`index` - the index of the source.

---

## **setSource**

```
public void setSource(java.lang.Object source,  
                      int index)
```

Sets one of the node's sources to an `Object`.

**Parameters:**

`source` - the source, as an `Object`.

`index` - the index of the source.

---

## **getByteParameter**

```
public byte getByteParameter(int index)
```

Returns one of the node's parameters, as a byte.

**Parameters:**

`index` - the index of the parameter.

---

## **getCharParameter**

```
public char getCharParameter(int index)
```

Returns one of the node's parameters, as a char.

**Parameters:**

`index` - the index of the parameter.

---

## **getShortParameter**

```
public short getShortParameter(int index)
```

Returns one of the node's parameters, as a short.

**Parameters:**

`index` - the index of the parameter.

---

### **getIntParameter**

```
public int getIntParameter(int index)
```

Returns one of the node's parameters, as an int.

**Parameters:**

- index - the index of the parameter.

---

### **getLongParameter**

```
public long getLongParameter(int index)
```

Returns one of the node's parameters, as a long.

**Parameters:**

- index - the index of the parameter.

---

### **getFloatParameter**

```
public float getFloatParameter(int index)
```

Returns one of the node's parameters, as a float.

**Parameters:**

- index - the index of the parameter.

---

### **getDoubleParameter**

```
public double getDoubleParameter(int index)
```

Returns one of the node's parameters, as a double.

**Parameters:**

- index - the index of the parameter.

---

### **getObjectParameter**

```
public java.lang.Object getObjectParameter(int index)
```

Returns one of the node's parameters, as an Object.

**Parameters:**

- index - the index of the parameter.

---

### **setParameter**

```
public void setParameter(byte param,  
                          int index)
```

Sets one of the node's parameters to a byte.

**Parameters:**

- param - the parameter, as a byte.
- index - the index of the parameter.

---

### **setParameter**

```
public void setParameter(char param,  
                          int index)
```

Sets one of the node's parameters to a char.

**Parameters:**

- param - the parameter, as a char.
- index - the index of the parameter.

---

### **setParameter**

```
public void setParameter(short param,  
                          int index)
```

Sets one of the node's parameters to a short.

**Parameters:**

- param - the parameter, as a short.
- index - the index of the parameter.

---

### setParameter

```
public void setParameter(int param,  
                        int index)
```

Sets one of the node's parameters to an int.

**Parameters:**

param - the parameter, as an int.  
index - the index of the parameter.

---

### setParameter

```
public void setParameter(long param,  
                        int index)
```

Sets one of the node's parameters to a long.

**Parameters:**

param - the parameter, as a long.  
index - the index of the parameter.

---

### setParameter

```
public void setParameter(float param,  
                        int index)
```

Sets one of the node's parameters to a float.

**Parameters:**

param - the parameter, as a float.  
index - the index of the parameter.

---

### setParameter

```
public void setParameter(double param,  
                        int index)
```

Sets one of the node's parameters to a double.

**Parameters:**

param - the parameter, as a double.  
index - the index of the parameter.

---

### setParameter

```
public void setParameter(java.lang.Object param,  
                        int index)
```

Sets one of the node's parameters to an Object.

**Parameters:**

param - the parameter, as an Object.  
index - the index of the parameter.

---

### writeObject

```
private void writeObject(java.io.ObjectOutputStream out)  
                throws java.io.IOException
```

Serialize the RenderableOp.

---

### readObject

```
private void readObject(java.io.ObjectInputStream in)  
                throws java.io.IOException,  
                        java.lang.ClassNotFoundException
```

Deserialize the RenderableOp.

---

## javax.media.jai Class RenderedImageAdapter

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|   |
|   +-- javax.media.jai.RenderedImageAdapter
```

### Direct Known Subclasses:

WritableRenderedImageAdapter

---

public class **RenderedImageAdapter**  
extends PlanarImage

A PlanarImage wrapper for a non-writable RenderedImage. The tile layout, sample model, and so forth are preserved. Calls to `getTile()` and so forth are forwarded.

From JAI's point of view, this image is a PlanarImage of unknown type, with no sources. The source image is assumed to be immutable. If the RenderedImage source implements WritableRenderedImage, a WritableRenderedImageAdapter should be used. The class and all its methods are marked 'final' in order to allow dynamic inlining to take place. This should eliminate any performance penalty associated with the use of an adapter class.

Since the methods of this class all derive from PlanarImage, they are not commented in detail.

### See Also:

PlanarImage, RenderedImage, WritableRenderedImage, WritableRenderedImageAdapter

---

## Field Detail

### theImage

protected java.awt.image.RenderedImage **theImage**  
The RenderedImage being adapted.

## Constructor Detail

### RenderedImageAdapter

public **RenderedImageAdapter**(java.awt.image.RenderedImage im)

Constructs a RenderedImageAdapter.

#### Parameters:

im - a RenderedImage to be 'wrapped' as a PlanarImage.

#### Throws:

java.lang.IllegalArgumentException - if im is null.

## Method Detail

### getProperty

public final java.lang.Object **getProperty**(java.lang.String name)

Forwards call to the true source.

#### Overrides:

getProperty in class PlanarImage

---

### getPropertyNames

public final java.lang.String[] **getPropertyNames**()

Forwards call to the true source.

#### Overrides:

getPropertyNames in class PlanarImage

---

## **getTile**

```
public final java.awt.image.Raster getTile(int x,  
                                           int y)
```

Forwards call to the true source.

### **Overrides:**

getTile in class PlanarImage

---

## **getData**

```
public final java.awt.image.Raster getData()
```

Forwards call to the true source.

### **Overrides:**

getData in class PlanarImage

---

## **getData**

```
public final java.awt.image.Raster getData(java.awt.Rectangle rect)
```

Forwards call to the true source.

### **Overrides:**

getData in class PlanarImage

---

## **copyData**

```
public final java.awt.image.WritableRaster copyData(java.awt.image.WritableRaster raster)
```

Forwards call to the true source.

### **Overrides:**

copyData in class PlanarImage

---

## javax.media.jai Class RenderedOp

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|
+-- javax.media.jai.RenderedOp
```

---

```
public class RenderedOp
    extends PlanarImage
    implements java.io.Serializable
```

A node in a rendered imaging chain. A `RenderedOp` stores an operation name (as a `String`), a `ParameterBlock` containing sources and miscellaneous parameters, and a `RenderingHints` containing rendering hints. A set of nodes may be joined together via the source `Vectors` within their `ParameterBlocks` to form a directed acyclic graph (DAG). The topology i.e., connectivity of the graph may be altered by changing the `ParameterBlocks`; the operation name, parameters, and rendering hints may also be changed.

Such chains are useful as arguments to a `RemoteImage`; they convey the structure of an imaging chain in a compact representation and at a suitably high level of abstraction to allow the server some leeway in materializing the results.

When any `RenderedImage` method is called on a `RenderedOp`, (any of `getWidth()`, `getHeight()`, `getMinX()`, `getMinY()`, `getNumXTiles()`, `getNumYTiles()`, `getMinTileX()`, `getMinTileY()`, `getTileWidth()`, `getTileHeight()`, `getTileGridXOffset()`, `getTileGridYOffset()`, `getTile()`, `getData()`, `copyData()`, `getColorModel()`, `getSampleModel()`, or `getProperty()` with a synthesized property name), the `RenderedOp` is implicitly rendered and becomes "frozen." Its operation name, `ParameterBlock`, and rendering hints may no longer be changed.

Furthermore, when some of the methods from `PlanarImage` are called, such as "get" and "set" methods on its source objects, the `RenderedOp` is implicitly rendered and becomes "frozen."

Serialization of a "frozen" node has the effect of "thawing" it; in other words, the instance variable holding the reference to the rendering of the node is transient and is not placed into the serialized byte stream. This allows working chains to be passed to a remote server using remote method invocation (RMI). Note that `RenderedOp` nodes used to instantiate operations which have a corresponding `OperationDescriptor` the `isImmediate()` method of which returns `true` are rendered upon deserialization.

A node may be rendered explicitly by means of the `createInstance()` method. This method returns a `PlanarImage` rendering without freezing the node. This allows a chain to be manipulated dynamically and rendered multiple times.

The translation between `RenderedOp` chains and `OpImage` chains makes use of two levels of indirection provided by the `OperationRegistry` and `RenderedImageFactory` (RIF) facilities. First, the local `OperationRegistry` is used to map the operation name into a RIF. This RIF then constructs one or more `OpImages` to do the actual work (or returns a `RenderedImage` by other means). The local `OperationRegistry` is used in order to take advantage of RIFs that are known to a server without having to burden the client.

`RenderedOp` represents a single `PlanarImage`; its companion class, `CollectionOp` represents `CollectionImage` nodes.

The `RenderedOp` synthesizes several property values, which may not be removed. These are: `image_width`, `image_height`, `image_min_x_coord`, and `image_min_y_coord`.

**See Also:**  
`CollectionOp`

---

### Field Detail

#### theImage

```
protected transient PlanarImage theImage
```

The rendering of the current image, not preserved over RMI.

#### theRegistry

```
private transient OperationRegistry theRegistry
```

The `OperationRegistry` that is used to render this node.

---

## operationName

private java.lang.String **operationName**  
The name of the operation this node represents.

---

## paramBlock

private transient java.awt.image.renderable.ParameterBlock **paramBlock**  
The input arguments for this operation, including sources and/or parameters.

---

## renderHints

private transient java.awt.RenderingHints **renderHints**  
The rendering hints to use for this operation.

---

## thePropertySource

protected transient PropertySource **thePropertySource**  
The PropertySource containing the combined properties of all of the node's sources.

---

## synthProps

private static java.util.Vector **synthProps**  
Names of synthesized properties.

---

## localProperties

private transient java.util.Hashtable **localProperties**  
Locally-stored properties.

---

## synthProperties

private java.util.Hashtable **synthProperties**  
Synthesized properties.

---

## volatilePropertyInfo

private java.util.Vector **volatilePropertyInfo**  
Cache of information in "thePropertySource" which is lost in the serialization/deserialization process. This includes the PropertyGenerators added via addPropertyGenerator() and the names of properties specified via suppressProperty(). The nature of each Vector element is determined by its class, i.e., String (name of a suppressed property) or PropertyGenerator.

## Constructor Detail

### RenderedOp

```
public RenderedOp(OperationRegistry registry,  
                  java.lang.String opName,  
                  java.awt.image.renderable.ParameterBlock pb,  
                  java.awt.RenderingHints hints)
```

Constructs a RenderedOp that will be used to instantiate a particular rendered operation from a given operation registry, an operation name, a ParameterBlock, and a set of rendering hints. All input parameters are saved by reference.

#### Parameters:

registry - The OperationRegistry to be used for instantiation. if null, the default registry is used.  
opName - The operation name.  
pb - The sources and other parameters. If null, it is assumed that this node has no sources and parameters.  
hints - The rendering hints. If null, it is assumed that no hints are associated with the rendering.

#### Throws:

NullPointerException - if opName is null.

---

## RenderedOp

```
public RenderedOp(java.lang.String opName,  
                  java.awt.image.renderable.ParameterBlock pb,  
                  java.awt.RenderingHints hints)
```

Constructs a `RenderedOp` that will be used to instantiate a particular rendered operation from a given operation registry, an operation name, a `ParameterBlock`, and a set of rendering hints. The default operation registry is used. All input parameters are saved by reference.

**Parameters:**

opName - The operation name.

pb - The sources and other parameters. If null, it is assumed that this node has no sources and parameters.

hints - The rendering hints. If null, it is assumed that no hints are associated with the rendering.

**Throws:**

`NullPointerException` - if opName is null.

## Method Detail

```
static void ()
```

## getRegistry

```
public OperationRegistry getRegistry()
```

Returns the `OperationRegistry` that is used by this node. If the registry had not been set, the default registry is returned.

## setRegistry

```
public void setRegistry(OperationRegistry registry)
```

Sets the `OperationRegistry` that is used by this node. If the specified registry is null, the default registry is used. If this node has been rendered and frozen, this method has no effect. The parameter is saved by reference.

**Parameters:**

registry - The new `OperationRegistry` to be set; it may be null.

## getOperationName

```
public java.lang.String getOperationName()
```

Returns the name of the operation this node represents as a `String`.

## setOperationName

```
public void setOperationName(java.lang.String opName)
```

Sets the name of the operation this node represents. If this node has been rendered and frozen, this method has no effect. The parameter is saved by reference.

**Parameters:**

opName - The new operation name to be set.

**Throws:**

`NullPointerException` - if opName is null.

## getParameterBlock

```
public java.awt.image.renderable.ParameterBlock getParameterBlock()
```

Returns the `ParameterBlock` of this node.

## setParameterBlock

```
public void setParameterBlock(java.awt.image.renderable.ParameterBlock pb)
```

Sets the `ParameterBlock` of this node. If this node has been rendered and frozen, this method has no effect. If the specified new `ParameterBlock` is null, it is assumed that this node has no input sources and parameters. The parameter is saved by reference.

This method does not validate the content of the supplied `ParameterBlock`. The caller should ensure that the sources and parameters in the `ParameterBlock` are suitable for the operation this node represents; otherwise some form of error or exception may occur at the time of rendering.

**Parameters:**

pb - The new ParameterBlock to be set; it may be null.

---

## getRenderingHints

```
public java.awt.RenderingHints getRenderingHints()
```

Returns the RenderingHints of this node. It may be null.

---

## setRenderingHints

```
public void setRenderingHints(java.awt.RenderingHints hints)
```

Sets the RenderingHints of this node. If this node has been rendered and frozen, this method has no effect. The parameter is saved by reference.

**Parameters:**

hints - The new RenderingHints to be set; it may be null.

---

## createInstance

```
public PlanarImage createInstance()
```

Instantiate a PlanarImage that computes the result of this RenderedOp. The default OperationRegistry is used to translate operation names into actual OpImages.

During this method, all the sources supplied in the ParameterBlock are checked. If any of the sources is a RenderedOp, a rendering of that source is created. This propagates all the way up to the top of the op chain. If any of the sources is a Collection, then the collection is passed to the operation as-is. If there is a RenderedOp anywhere in the collection, it is up to the individual operation to create the rendering for that RenderedOp.

This method does not validate the sources and parameters stored in the ParameterBlock against the specification of the operation this node represents. It is the responsibility of the caller to ensure that the data in the ParameterBlock are suitable for this operation. Otherwise, some kind of exception or error will occur.

**Returns:**

The resulting image as a PlanarImage.

---

## createInstance

```
private PlanarImage createInstance(boolean isChainFrozen)
```

This method performs the actions described by the documentation of createInstance() optionally freezing the image chain as a function of the parameter.

---

## createRendering

```
private void createRendering()
```

Creates an RenderedImage rendering if none exists.

---

## getRendering

```
public PlanarImage getRendering()
```

Returns the PlanarImage rendering associated with this RenderedOp node.

This method does not validate the sources and parameters stored in the ParameterBlock against the specification of the operation this node represents. It is the caller's responsibility to ensure that the data in the ParameterBlock are suitable for this operation. Otherwise, an exception or error will occur.

---

## createPropertySource

```
private void createPropertySource()
```

Creates a PropertySource if none exists.

---

## createVolatilePropertyVector

```
private void createVolatilePropertyVector()
```

Creates a volatile property info Vector if none exists.

---

## getPropertyNames

```
public java.lang.String[] getPropertyNames()
```

Returns the names of properties available from this node. These properties are a combination of those derived from prior nodes in the imaging chain, those set locally, and a number of locally derived, immutable properties based on the rendering associated with this node -- height, width, and so forth.

**Returns:**  
An array of Strings containing valid property names.

**Overrides:**  
getPropertyNames in class PlanarImage

---

## createSynthProperties

```
private void createSynthProperties()
```

Initialize the synthProperties Hashtable if needed.

---

## createLocalProperties

```
private void createLocalProperties()
```

Initialize the localProperties Hashtable if needed.

---

## getProperty

```
public java.lang.Object getProperty(java.lang.String name)
```

Returns the property associated with the specified property name, or `java.awt.Image.UndefinedProperty` if the specified property is not set on the image.

**Parameters:**  
name - A String naming the property.

**Throws:**  
`java.lang.IllegalArgumentException` - if name is null.

**Overrides:**  
getProperty in class PlanarImage

---

## setProperty

```
public void setProperty(java.lang.String name,  
                        java.lang.Object value)
```

Sets a local property on a node. The synthetic properties (containing image width, height, and position) may not be set. Local property settings override properties derived from prior nodes in the imaging chain.

Properties may be set on a `RenderedOp` node only prior to the creation of a rendering at that node. In general this means that `setProperty()` should be called only immediately after construction of a node.

If the node is serialized then serializable properties will also be serialized but non-serializable properties will be lost.

**Parameters:**  
name - A String representing the property name.  
value - The property's value, as an Object.

**Throws:**  
`RuntimeException` - if method is called on a rendered node.  
`RuntimeException` - if name conflicts with Synthetic property.  
`IllegalArgumentException` - if name is null.  
`IllegalArgumentException` - if value is null.

**Overrides:**  
setProperty in class PlanarImage

---

## addPropertyGenerator

public void **addPropertyGenerator**(PropertyGenerator pg)

Adds a PropertyGenerator to the node. The property values emitted by this property generator override any previous definitions.

**Parameters:**

pg - A PropertyGenerator to be added to this node's property environment.

**Throws:**

IllegalArgumentException - if pg is null.

---

## suppressProperty

public void **suppressProperty**(java.lang.String name)

Removes a named property from the property environment of this node. Subsequent calls to `getProperty(name)` will return null, and name will not appear on the list of properties emitted by `getPropertyNames()`.

**Parameters:**

name - A String naming the property to be suppressed.

**Throws:**

IllegalArgumentException - if name is null.

RuntimeException - if name conflicts with Synthetic property.

---

## writeObject

private void **writeObject**(java.io.ObjectOutputStream out)  
throws java.io.IOException

Serializes the RenderedOp.

---

## readObject

private void **readObject**(java.io.ObjectInputStream in)  
throws java.io.IOException,  
java.lang.ClassNotFoundException

Deserialize the RenderedOp.

---

## getNumSources

public int **getNumSources**()

Returns the number of sources stored in the ParameterBlock of this node. This may differ from the number of sources of the rendered image.

**Overrides:**

getNumSources in class PlanarImage

---

## getSources

public java.util.Vector **getSources**()

Returns the sources stored in the ParameterBlock of this node. This may differ from the source vector of the rendered image.

**Overrides:**

getSources in class PlanarImage

---

## getNodeSource

public java.lang.Object **getNodeSource**(int index)

---

## addNodeSource

public void **addNodeSource**(java.lang.Object source)

Adds a source to the ParameterBlock of this node. If this node has been rendered, this method has no effect.

**Parameters:**

source - The source to be added to the ParameterBlock

---

## setSources

public void **setSources**(java.util.List sourceList)

Replaces the sources in the ParameterBlock of this node with a new list of sources. If this node has been rendered, this method has no effect.

**Parameters:**

sourceList - A List of sources.

**Throws:**

java.lang.IllegalArgumentException - if sourceList is null.

**Overrides:**

setSources in class PlanarImage

---

## setNodeSource

public void **setNodeSource**(java.lang.Object source,  
int index)

Sets the specified source stored in the ParameterBlock of this node to a new source object. If this node has been rendered, this method has no effect.

**Parameters:**

source - The Source to be set.

index - The Index at which it is to be set.

**Throws:**

java.lang.IllegalArgumentException - if source is null.

ArrayIndexOutOfBoundsException - if index is invalid.

---

## removeSources

public void **removeSources**()

Removes all the sources stored in the ParameterBlock of this node. If this node has been rendered, this method has no effect.

**Overrides:**

removeSources in class PlanarImage

---

## getNumParameters

public int **getNumParameters**()

Returns the number of parameters stored in the ParameterBlock of this node.

---

## getParameters

public java.util.Vector **getParameters**()

Returns the parameters stored in the ParameterBlock of this node.

---

## getBytesParameter

public byte **getBytesParameter**(int index)

Returns the specified parameter stored in the ParameterBlock of this node as a byte. An ArrayIndexOutOfBoundsException may occur if an invalid index is supplied

**Parameters:**

index - The index of the parameter.

**Throws:**

ArrayIndexOutOfBoundsException - if index is invalid.

---

## getCharParameter

public char **getCharParameter**(int index)

Returns the specified parameter stored in the ParameterBlock of this node as a char. An ArrayIndexOutOfBoundsException may occur if an invalid index is supplied

**Parameters:**

index - The index of the parameter.

**Throws:**  
ArrayIndexOutOfBoundsException - if index is invalid.

---

### getShortParameter

public short **getShortParameter**(int index)  
Returns the specified parameter stored in the ParameterBlock of this node as a short. An ArrayIndexOutOfBoundsException may occur if an invalid index is supplied  
**Parameters:**  
index - The index of the parameter.  
**Throws:**  
ArrayIndexOutOfBoundsException - if index is invalid.

---

### getIntParameter

public int **getIntParameter**(int index)  
Returns the specified parameter stored in the ParameterBlock of this node as an int. An ArrayIndexOutOfBoundsException may occur if an invalid index is supplied  
**Parameters:**  
index - The index of the parameter.  
**Throws:**  
ArrayIndexOutOfBoundsException - if index is invalid.

---

### getLongParameter

public long **getLongParameter**(int index)  
Returns the specified parameter stored in the ParameterBlock of this node as a long. An ArrayIndexOutOfBoundsException may occur if an invalid index is supplied  
**Parameters:**  
index - The index of the parameter.  
**Throws:**  
ArrayIndexOutOfBoundsException - if index is invalid.

---

### getFloatParameter

public float **getFloatParameter**(int index)  
Returns the specified parameter stored in the ParameterBlock of this node as a float. An ArrayIndexOutOfBoundsException may occur if an invalid index is supplied  
**Parameters:**  
index - The index of the parameter.  
**Throws:**  
ArrayIndexOutOfBoundsException - if index is invalid.

---

### getDoubleParameter

public double **getDoubleParameter**(int index)  
Returns the specified parameter stored in the ParameterBlock of this node as a double. An ArrayIndexOutOfBoundsException may occur if an invalid index is supplied  
**Parameters:**  
index - The index of the parameter.  
**Throws:**  
ArrayIndexOutOfBoundsException - if index is invalid.

---

### getObjectParameter

public java.lang.Object **getObjectParameter**(int index)  
Returns the specified parameter stored in the ParameterBlock of this node as an Object. An ArrayIndexOutOfBoundsException may occur if an invalid index is supplied  
**Parameters:**  
index - The index of the parameter.  
**Throws:**  
ArrayIndexOutOfBoundsException - if index is invalid.

---

## setParameter

```
public void setParameter(byte param,  
                          int index)
```

Sets one of the node's parameters to a byte. If the node has been rendered, this has no effect. If the `index` lies beyond the current source list, the list is extended with nulls as needed.

**Parameters:**

`param` - The parameter, as a byte.  
`index` - The index of the parameter.

---

## setParameter

```
public void setParameter(char param,  
                          int index)
```

Sets one of the node's parameters to a char. If the node has been rendered, this has no effect. If the `index` lies beyond the current source list, the list is extended with nulls as needed.

**Parameters:**

`param` - The parameter, as a char.  
`index` - The index of the parameter.

---

## setParameter

```
public void setParameter(short param,  
                          int index)
```

Sets one of the node's parameters to a short. If the node has been rendered, this has no effect. If the `index` lies beyond the current source list, the list is extended with nulls as needed.

**Parameters:**

`param` - The parameter, as a short.  
`index` - The index of the parameter.

---

## setParameter

```
public void setParameter(int param,  
                          int index)
```

Sets one of the node's parameters to an int. If the node has been rendered, this has no effect. If the `index` lies beyond the current source list, the list is extended with nulls as needed.

**Parameters:**

`param` - The parameter, as an int.  
`index` - The index of the parameter.

---

## setParameter

```
public void setParameter(long param,  
                          int index)
```

Sets one of the node's parameters to a long. If the node has been rendered, this has no effect. If the `index` lies beyond the current source list, the list is extended with nulls as needed.

**Parameters:**

`param` - The parameter, as a long.  
`index` - The index of the parameter.

---

## setParameter

```
public void setParameter(float param,  
                          int index)
```

Sets one of the node's parameters to a float. If the node has been rendered, this has no effect. If the `index` lies beyond the current source list, the list is extended with nulls as needed.

**Parameters:**

`param` - The parameter, as a float.  
`index` - The index of the parameter.

---

## setParameter

```
public void setParameter(double param,  
                          int index)
```

Sets one of the node's parameters to a double. If the node has been rendered, this has no effect. If the `index` lies beyond the current source list, the list is extended with nulls as needed.

**Parameters:**

`param` - The parameter, as a double.  
`index` - The index of the parameter.

---

## setParameter

```
public void setParameter(java.lang.Object param,  
                          int index)
```

Sets one of the node's parameters to an Object. If the node has been rendered, this has no effect. If the `index` lies beyond the current source list, the list is extended with nulls as needed.

**Parameters:**

`param` - The parameter, as an Object.  
`index` - The index of the parameter.

---

## getMinX

```
public int getMinX()
```

Renders the node if it has not already been rendered, and returns the X coordinate of the leftmost column of the rendered image.

**Overrides:**

`getMinX` in class `PlanarImage`

---

## getMaxX

```
public int getMaxX()
```

Renders the node if it has not already been rendered, and returns the X coordinate of the column immediately to the right of the rightmost column of the rendered image.

**Overrides:**

`getMaxX` in class `PlanarImage`

---

## getMinY

```
public int getMinY()
```

Renders the node if it has not already been rendered, and returns the X coordinate of the uppermost row of the rendered image.

**Overrides:**

`getMinY` in class `PlanarImage`

---

## getMaxY

```
public int getMaxY()
```

Renders the node if it has not already been rendered, and returns the Y coordinate of the row immediately below the bottom row of the rendered image.

**Overrides:**

`getMaxY` in class `PlanarImage`

---

## getWidth

```
public int getWidth()
```

Renders the node if it has not already been rendered, and returns the width of the rendered image.

**Overrides:**

`getWidth` in class `PlanarImage`

---

## getHeight

public int **getHeight**()

Renders the node if it has not already been rendered, and returns the height of the rendered image.

**Overrides:**

getHeight in class PlanarImage

---

## getTileWidth

public int **getTileWidth**()

Renders the node if it has not already been rendered, and returns the tile width of the rendered image.

**Overrides:**

getTileWidth in class PlanarImage

---

## getTileHeight

public int **getTileHeight**()

Renders the node if it has not already been rendered, and returns the tile height of the rendered image.

**Overrides:**

getTileHeight in class PlanarImage

---

## getTileGridXOffset

public int **getTileGridXOffset**()

Renders the node if it has not already been rendered, and returns the tile grid X offset of the rendered image.

**Overrides:**

getTileGridXOffset in class PlanarImage

---

## getTileGridYOffset

public int **getTileGridYOffset**()

Renders the node if it has not already been rendered, and returns the tile grid Y offset of the rendered image.

**Overrides:**

getTileGridYOffset in class PlanarImage

---

## getSampleModel

public java.awt.image.SampleModel **getSampleModel**()

Renders the node if it has not already been rendered, and returns the SampleModel of the rendered image.

**Overrides:**

getSampleModel in class PlanarImage

---

## getColorModel

public java.awt.image.ColorModel **getColorModel**()

Renders the node if it has not already been rendered, and returns the ColorModel of the rendered image.

**Overrides:**

getColorModel in class PlanarImage

---

## getTile

public java.awt.image.Raster **getTile**(int tileX,  
int tileY)

Renders the node if it has not already been rendered, and returns the specified tile of the rendered image.

**Parameters:**

tileX - The X index of the tile.

tileY - The Y index of the tile.

**Returns:**

The requested tile as a Raster.

**Overrides:**

getTile in class PlanarImage

---

## getTiles

```
public java.awt.image.Raster[] getTiles(java.awt.Point[] tileIndices)
```

Renders the node if it has not already been rendered, and returns the tiles indicated by the `tileIndices` of the rendered image as an array of Rasters.

**Parameters:**

`tileIndices` - An array of Points representing TileIndices.

**Returns:**

An array of Raster containing the tiles corresponding to the given TileIndices.

**Overrides:**

`getTiles` in class `PlanarImage`

---

## prefetchTiles

```
public void prefetchTiles(java.awt.Point[] tileIndices)
```

Renders the node if it has not already been rendered. Hints that the given tiles of the rendered image might be needed in the near future.

**Parameters:**

`tileIndices` - A list of tileIndices indicating which tiles to prefetch.

**Overrides:**

`prefetchTiles` in class `PlanarImage`

---

## getData

```
public java.awt.image.Raster getData()
```

Renders the node if it has not already been rendered, and returns the entire rendered image as a Raster.

**Overrides:**

`getData` in class `PlanarImage`

---

## getData

```
public java.awt.image.Raster getData(java.awt.Rectangle rect)
```

Renders the node if it has not already been rendered, and returns a specified rectangular region of the rendered image as a Raster.

**Overrides:**

`getData` in class `PlanarImage`

---

## copyData

```
public java.awt.image.WritableRaster copyData()
```

Renders the node if it has not already been rendered, and copies and returns the entire rendered image into a single raster.

**Overrides:**

`copyData` in class `PlanarImage`

---

## copyData

```
public java.awt.image.WritableRaster copyData(java.awt.image.WritableRaster raster)
```

Renders the node if it has not already been rendered, and copies a specified rectangle of the rendered image into the given `WritableRaster`.

**Parameters:**

`raster` - A `WritableRaster` to be filled with image data.

**Returns:**

A reference to the supplied `WritableRaster`.

**Overrides:**

`copyData` in class `PlanarImage`

---

## getSource

```
public PlanarImage getSource(int index)
```

Renders the node if it has not already been rendered, and returns the specified `PlanarImage` source of the rendered image. If there is no source corresponding to the specified index, this method will throw an `ArrayIndexOutOfBoundsException`. The source returned may differ from the source stored in the `ParameterBlock` of this node.

**Parameters:**

index - The index of the desired source.

**Returns:**

A PlanarImage source.

**Overrides:**

getSource in class PlanarImage

---

**addSource**

```
public void addSource(PlanarImage source)
```

Renders the node if it has not already been rendered, and adds a PlanarImage source to the list of sources of the rendered image.

**Parameters:**

source - A PlanarImage to be added as a source.

**Throws:**

IllegalArgumentException - if source is null.

**Overrides:**

addSource in class PlanarImage

---

**removeSource**

```
public boolean removeSource(PlanarImage source)
```

Renders the node if it has not already been rendered, and removes a PlanarImage source from the list of sources of the rendered image.

**Parameters:**

source - A PlanarImage to be removed.

**Returns:**

true if the element was present, false otherwise.

**Throws:**

IllegalArgumentException - if source is null.

**Overrides:**

removeSource in class PlanarImage

---

**setSource**

```
public void setSource(PlanarImage source,  
                     int index)
```

Renders the node if it has not already been rendered, and sets the specified source of the rendered image to the supplied PlanarImage. An ArrayIndexOutOfBoundsException may be thrown if an invalid index is supplied

**Parameters:**

source - The source, as a PlanarImage.

index - The index of the source.

**Overrides:**

setSource in class PlanarImage

---

**getSinks**

```
public java.util.Vector getSinks()
```

Renders the node if it has not already been rendered, and returns a Vector containing the currently available PlanarImage sinks of the rendered image, or null if no sinks are present.

**Overrides:**

getSinks in class PlanarImage

---

**addSink**

```
public void addSink(PlanarImage sink)
```

Renders the node if it has not already been rendered, and adds a PlanarImage sink to the list of sinks of the rendered image.

**Throws:**

IllegalArgumentException - if sink is null.

**Overrides:**

addSink in class PlanarImage

---

## **removeSink**

`public boolean removeSink(PlanarImage sink)`

Renders the node if it has not already been rendered, and removes a `PlanarImage` sink from the list of sinks of the rendered image.

**Throws:**

`IllegalArgumentException` - if sink is null.

**Overrides:**

`removeSink` in class `PlanarImage`

---

## javax.media.jai Class ScaleOpImage

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|   |
|   +-- javax.media.jai.OpImage
|       |
|       +-- javax.media.jai.WarpOpImage
|           |
|           +-- javax.media.jai.ScaleOpImage
```

---

public abstract class **ScaleOpImage**  
extends **WarpOpImage**

A class extending **WarpOpImage** for use by further extension classes that perform image scaling. Image scaling operations require rectilinear backwards mapping and padding by the resampling filter dimensions.

When applying scale factors of *scaleX*, *scaleY* to a source image with width of *src\_width* and height of *src\_height*, the resulting image is defined to have the following bounds: *dst min X* = floor(*src min X* \* *scaleX* + *transX*) *dst min Y* = floor(*src min Y* \* *scaleY* + *transY*) *dst width* = ceil(*src width* \* *scaleX*) *dst height* = ceil(*src height* \* *scaleY*)

When interpolations which require padding the source such as Bilinear or Bicubic interpolation are specified, the source needs to be extended such that it has the extra pixels needed to compute all the destination pixels. This extension is performed via the **BorderExtender** class. The type of border extension can be specified as a **RenderingHint** to the **JAI.create** method.

If no **BorderExtender** is specified, the source will not be extended. The scaled image size is still calculated according to the formula specified above. However since there is not enough source to compute all the destination pixels, only that subset of the destination image's pixels which can be computed, will be written in the destination. The rest of the destination will be set to zeros.

**Constructor Detail**

**ScaleOpImage**

```
public ScaleOpImage( java.awt.image.RenderedImage source,
                    BorderExtender extender,
                    TileCache cache,
                    ImageLayout layout,
                    float scaleX,
                    float scaleY,
                    float transX,
                    float transY,
                    Interpolation interp,
                    boolean cobbleSources)
```

Constructs a `ScaleOpImage` from a `RenderedImage` source, an optional `BorderExtender`, x and y scale and translation factors, and an `Interpolation` object. The image dimensions are determined by forward-mapping the source bounds, and are passed to the superclass constructor by means of the `layout` parameter. Other fields of the layout are passed through unchanged. If `layout` is null, a new `ImageLayout` will be constructor to hold the bounds information. Note that the scale factors are represented internally as `Rational` numbers in order to workaround inexact device specific representation of floating point numbers. For instance the floating point number 1.2 is internally represented as 1.200001, which can throw the calculations off during a forward/backward map.

The `Rational` approximation is valid upto the sixth decimal place.

**Parameters:**

`source` - a `RenderedImage`.  
`extender` - a `BorderExtender`, or null.  
`cache` - a `TileCache` object to store tiles from this `OpImage`, or null. If null, a default cache will be used.  
`layout` - an `ImageLayout` optionally containing the tile grid layout, `SampleModel`, and `ColorModel`, or null.  
`scaleX` - scale factor along x axis.  
`scaleY` - scale factor along y axis.  
`transX` - translation factor along x axis.  
`transY` - translation factor along y axis.  
`interp` - an `Interpolation` object to use for resampling.  
`cobbleSources` - a boolean indicating whether `computeRect` expects contiguous sources.

**Throws:**

`java.lang.IllegalArgumentException` - if combining the source bounds with the layout parameter results in negative output width or height.

## Method Detail

### layoutHelper

```
private static ImageLayout layoutHelper(java.awt.image.RenderedImage source,
                                       float scaleX,
                                       float scaleY,
                                       float transX,
                                       float transY,
                                       ImageLayout il)
```

### mapSourceRect

```
public java.awt.Rectangle mapSourceRect(java.awt.Rectangle sourceRect,
                                       int sourceIndex)
```

Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**Parameters:**

`sourceRect` - the `Rectangle` in source coordinates.  
`sourceIndex` - the index of the source image.

**Returns:**

a `Rectangle` indicating the potentially affected destination region. or null if the region is unknown.

**Throws:**

`java.lang.IllegalArgumentException` - if the source index is negative or greater than that of the last source.  
`NullPointerException` - if `sourceRect` is null.

**Overrides:**

`mapSourceRect` in class `WarpOpImage`

### mapDestRect

```
public java.awt.Rectangle mapDestRect(java.awt.Rectangle destRect,
                                       int sourceIndex)
```

Returns a conservative estimate of the region of a specified source that is required in order to compute the pixels of a given destination rectangle.

**Parameters:**

`destRect` - the `Rectangle` in destination coordinates.  
`sourceIndex` - the index of the source image.

**Returns:**

a `Rectangle` indicating the required source region.

**Throws:**

`java.lang.IllegalArgumentException` - if the source index is negative or greater than that of the last source.  
`NullPointerException` - if `destRect` is null.

**Overrides:**

mapDestRect in class WarpOpImage

---

**computeTile**

```
public java.awt.image.Raster computeTile(int tileX,  
                                           int tileY)
```

Computes a tile. If source cobbling was requested at construction time, the source tile boundaries are overlayed onto the destination, cobbling is performed for areas that intersect multiple source tiles, and computeRect(Raster[], WritableRaster, Rectangle) is called for each of the resulting regions. Otherwise, computeRect(PlanarImage[], WritableRaster, Rectangle) is called once to compute the entire active area of the tile.

The image bounds may be larger than the bounds of the source image. In this case, samples for which there are no corresponding sources are set to zero.

The following steps are performed in order to compute the tile: - The destination tile is backward mapped to compute the needed source. - This source is then split on tile boundaries to produce rectangles that do not cross tile boundaries. - These source rectangles are then forward mapped to produce destination rectangles, and the computeRect method is called for each corresponding pair of source and destination rectangles. - For higher order interpolations, some source cobbling across tile boundaries does occur.

**Parameters:**

tileX - The X index of the tile.  
tileY - The Y index of the tile.

**Returns:**

The tile as a Raster.

**Overrides:**

computeTile in class WarpOpImage

---

## javax.media.jai Class SequentialImage

```
java.lang.Object
|
+-- javax.media.jai.SequentialImage
```

---

public class **SequentialImage**

extends java.lang.Object

A class representing an image that is associated with a time stamp and a camera position. This class is used with ImageSequence.

**See Also:**

ImageSequence

---

### Field Detail

#### image

public PlanarImage **image**

The image.

---

#### timeStamp

public float **timeStamp**

The time stamp associated with the image.

---

#### cameraPosition

public java.lang.Object **cameraPosition**

The camera position associated with the image. The type of this parameter is Object so that the application may choose any class to represent a camera position based on the individual's needs.

---

### Constructor Detail

#### SequentialImage

```
public SequentialImage(PlanarImage pi,
                       float ts,
                       java.lang.Object cp)
```

Constructor.

**Throws:**

NullPointerException - if pi is null.

NullPointerException - if cp is null.

---

## javax.media.jai Class Snapshot

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|   |
|   +-- javax.media.jai.Snapshot
```

---

final class **Snapshot**  
extends PlanarImage

A non-public class that holds a portion of the state associated with a SnapshotImage. A Snapshot provides the appearance of a PlanarImage with fixed contents. In order to provide this illusion, however, the Snapshot relies on the fact that it belongs to a linked list of Snapshots rooted in a particular SnapshotImage; it cannot function independently.

---

### Field Detail

#### parent

SnapshotImage **parent**  
The creator of this image.

---

#### next

Snapshot **next**  
The next Snapshot in a doubly-linked list.

---

#### prev

Snapshot **prev**  
The previous Snapshot in a doubly-linked list.

---

#### tiles

java.util.Hashtable **tiles**  
A set of cached TileCopy elements.

---

#### disposed

boolean **disposed**  
True if dispose() has been called.

---

### Constructor Detail

#### Snapshot

**Snapshot**(SnapshotImage parent)  
Constructs a Snapshot that will provide a synchronous view of a SnapshotImage at a particular moment in time.  
**Parameters:**  
parent - a SnapshotImage this image will be viewing.

---

### Method Detail

#### getTile

```
public java.awt.image.Raster getTile(int tileX,  
                                       int tileY)
```

Returns the version of a tile "seen" by this Snapshot. The tile "seen" is the oldest copy of the tile made after the creation of this Snapshot; it may be held in the tiles Hashtable of this Snapshot or one of its successors. If no later Snapshot holds a copy of the tile, the current version of the tile from the source image is returned.

getTile is synchronized in order to prevent calls to dispose(), which will cause the list of Snapshots to change, from occurring at the same time as the walking of the list.

**Parameters:**

tileX - the X index of the tile.

tileY - the Y index of the tile.

**Returns:**

the tile as a Raster.

**Overrides:**

getTile in class PlanarImage

---

## setNext

void **setNext**(Snapshot next)

Sets the next Snapshot in the list to a given Snapshot.

**Parameters:**

next - the next Snapshot in the list.

---

## setPrev

void **setPrev**(Snapshot prev)

Sets the previous Snapshot in the list to a given Snapshot.

**Parameters:**

prev - the previous Snapshot in the list.

---

## hasTile

boolean **hasTile**(int tileX,  
int tileY)

Returns true if this Snapshot already stores a version of a specified tile.

**Parameters:**

tileX - the X index of the tile.

tileY - the Y index of the tile.

**Returns:**

true if this Snapshot holds a copy of the tile.

---

## addTile

void **addTile**(java.awt.image.Raster tile,  
int tileX,  
int tileY)

Stores a given tile in this Snapshot. The caller should not attempt to store more than one version of a given tile.

**Parameters:**

tile - a Raster containing the tile data.

tileX - the tile's column within the image tile grid.

tileY - the tile's row within the image tile grid.

---

## dispose

public void **dispose**()

This image will no longer be referenced by the user.

**Overrides:**

dispose in class PlanarImage

---

## javax.media.jai Class SnapshotImage

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|   |
|   +-- javax.media.jai.SnapshotImage
```

---

```
public class SnapshotImage
    extends PlanarImage
    implements java.awt.image.TileObserver
```

A class providing an arbitrary number of synchronous views of a possibly changing WritableRenderedImage. SnapshotImage is responsible for stabilizing changing sources in order to allow deferred execution of operations dependent on such sources.

Any RenderedImage may be used as the source of a SnapshotImage; if it is a WritableRenderedImage, the SnapshotImage will register itself as a TileObserver and make copies of tiles that are about to change. Multiple versions of each tile are maintained internally, as long as they are in demand. SnapshotImage is able to track demand and should be able to simply forward requests for tiles to the source most of the time, without the need to make a copy.

When used as a source, calls to getTile will simply be passed along to the source. In other words, SnapshotImage is completely transparent. However, by calling createSnapshot() an instance of a non-public PlanarImage subclass (called Sanpshot in this implementation) will be created and returned. This image will always return tile data with contents as of the time of its construction.

When a particular Snapshot is no longer needed, its dispose() method may be called. The dispose() method will be called automatically when the Snapshot is finalized by the garbage collector. Disposing of the Snapshot allows tile data held by the Snapshot that is not needed by any other Snapshot to be disposed of as well.

This implementation of SnapshotImage makes use of a doubly-linked list of Snapshot objects. A new Snapshot is added to the tail of the list whenever createSnapshot() is called. Each Snapshot has a cache containing copies of any tiles that were writable at the time of its construction, as well as any tiles that become writable between the time of its construction and the construction of the next Snapshot.

When asked for a tile, a Snapshot checks its local cache and returns its version of the tile if one is found. Otherwise, it forwards the request onto its successor. This process continues until the latest Snapshot is reached; if it does not contain a copy of the tile, the tile is requested from the real source image.

When a Snapshot is no longer needed, its dispose() method attempts to push the contents of its tile cache back to the previous Snapshot in the linked list. If that image possesses a version of the same tile, the tile is not pushed back and may be discarded.

### See Also:

RenderedImage, TileObserver, WritableRenderedImage, PlanarImage

---

## Field Detail

### source

```
private PlanarImage source
```

The real image source.

---

### tail

```
private Snapshot tail
```

The last entry in the list of Snapshots, initially null.

---

### activeTiles

```
private java.util.HashSet activeTiles
```

The set of active tiles, represented as a HashSet of Points.

---

## Constructor Detail

---

## SnapshotImage

public **SnapshotImage**(PlanarImage source)

Constructs a SnapshotImage from a PlanarImage source.

**Parameters:**

source - a PlanarImage source.

**Throws:**

java.lang.IllegalArgumentException - if source is null.

## Method Detail

### getTrueSource

protected PlanarImage **getTrueSource**()

Returns the PlanarImage source of this SnapshotImage.

**Returns:**

a PlanarImage that is the source of data for this image.

### setTail

void **setTail**(Snapshot tail)

Sets the reference to the most current Snapshot to a given Snapshot.

**Parameters:**

tail - a reference to the new most current Snapshot.

### getTail

Snapshot **getTail**()

Returns a reference to the most current Snapshot.

**Returns:**

the Snapshot at the tail end of the list.

### createTileCopy

private java.awt.image.Raster **createTileCopy**(int tileX,  
int tileY)

Creates and returns a Raster copy of a given source tile.

**Parameters:**

tileX - the X index of the tile.

tileY - the Y index of the tile.

**Returns:**

a newly-constructed Raster containing a copy of the tile data.

### createSnapshot

public PlanarImage **createSnapshot**()

Creates a snapshot of this image. This snapshot may be used indefinitely, and will always appear to have the pixel data that this image has currently. The snapshot is semantically a copy of this image but may be implemented in a more efficient manner. Multiple snapshots taken at different times may share tiles that have not changed, and tiles that are currently static in this image's source do not need to be copied at all.

**Returns:**

a PlanarImage snapshot.

**Overrides:**

createSnapshot in class PlanarImage

### tileUpdate

public void **tileUpdate**(java.awt.image.WritableRenderedImage source,  
int tileX,  
int tileY,  
boolean willBeWritable)

Receives the information that a tile is either about to become writable, or is about to become no longer writable.

**Specified by:**

tileUpdate in interface java.awt.image.TileObserver

**Parameters:**

source - the WritableRenderedImage for which we are an observer.

tileX - the X index of the tile.

tileY - the Y index of the tile.

willBeWritable - true if the tile is becoming writable.

---

**getTile**

```
public java.awt.image.Raster getTile(int tileX,  
                                     int tileY)
```

Returns a non-snapshotted tile from the source.

**Parameters:**

tileX - the X index of the tile.

tileY - the Y index of the tile.

**Returns:**

the tile as a Raster.

**Overrides:**

getTile in class PlanarImage

---

## javax.media.jai Class SnapshotProxy

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|   |
|   +-- javax.media.jai.SnapshotProxy
```

---

final class **SnapshotProxy**  
extends PlanarImage

A proxy for Snapshot that calls Snapshot.dispose() when finalized. No references to a SnapshotProxy are held internally, only user references. Thus it will be garbage collected when the last user reference is relinquished. The Snapshot's dispose() method is called from SnapshotProxy.finalize(), ensuring that all of the resources held by the Snapshot will become collectable.

---

### Field Detail

#### parent

Snapshot **parent**

The parent Snapshot to which we forward getTile() calls.

### Constructor Detail

#### SnapshotProxy

**SnapshotProxy**(Snapshot parent)

Construct a new proxy for a given Snapshot.

**Parameters:**

parent - the Snapshot to which method calls will be forwarded.

### Method Detail

#### getTile

```
public java.awt.image.Raster getTile(int tileX,  
                                     int tileY)
```

Forwards a tile request to the parent Snapshot.

**Parameters:**

tileX - the X index of the tile.

tileY - the Y index of the tile.

**Returns:**

the tile as a Raster.

**Overrides:**

getTile in class PlanarImage

---

#### dispose

```
public void dispose()
```

Disposes of resources held by this proxy.

**Overrides:**

dispose in class PlanarImage

---

## javax.media.jai

### Class SourcelessOpImage

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|   |
|   +-- javax.media.jai.OpImage
|       |
|       +-- javax.media.jai.SourcelessOpImage
```

---

public abstract class **SourcelessOpImage**  
extends OpImage

An abstract base class for image operators that have no image sources.

SourcelessOpImage is intended as a convenient superclass for OpImages that have no source image. Some examples are constant color images, file readers, protocol-based network readers, and mathematically-defined imagery such as fractals.

The computeTile method of this class will call the computeRect(PlanarImage[], WritableRaster, Rectangle) method of the subclass to perform the computation. The first argument will be null as there are no source images.

#### See Also:

PointOpImage

---

## Constructor Detail

### SourcelessOpImage

```
public SourcelessOpImage(int minX,  
                        int minY,  
                        int width,  
                        int height,  
                        java.awt.image.SampleModel sampleModel,  
                        TileCache cache,  
                        ImageLayout layout)
```

Constructs a SourcelessOpImage. The image bounds and SampleModel are set explicitly; other layout parameters may be set using the layout parameter. The min X, min Y, width, height, and SampleModel fields of the layout parameter are ignored.

If sampleModel is null, no exceptions will be thrown. However, the caller must be sure to set the sampleModel instance variable before construction terminates. This feature allows subclasses that require external computation such as file loading to defer the determination of their SampleModel until after the call to super.

Similarly, minX, minY, width, and height may be dummy values if care is taken to manually set all values that depend on them, namely the tile grid offset, tile size, and SampleModel width and height.

The tile dimensions, tile grid X and Y offsets, and ColorModel of the output will be set in the standard way by the OpImage constructor.

#### Parameters:

cache - a TileCache object to store tiles from this OpImage, or null. If null, a default cache will be used.  
layout - an ImageLayout describing the layout.

---

## Method Detail

### layoutHelper

```
private static ImageLayout layoutHelper(int minX,  
                                       int minY,  
                                       int width,  
                                       int height,  
                                       java.awt.image.SampleModel sampleModel,  
                                       ImageLayout il)
```

---

## computesUniqueTiles

```
public boolean computesUniqueTiles()
```

Returns false as SourcelessOpImages often return Rasters via computeTile() tile that are internally cached. Some subclasses may want to override this method and return true.

**Overrides:**

computesUniqueTiles in class OpImage

---

## computeTile

```
public java.awt.image.Raster computeTile(int tileX,  
                                           int tileY)
```

Computes a tile. Since the operation has no sources, there is no need to worry about cobbling.

Subclasses should implement the computeRect(PlanarImage[], WritableRaster, Rectangle) method to perform the actual computation.

**Parameters:**

tileX - The X index of the tile.

tileY - The Y index of the tile.

**Overrides:**

computeTile in class OpImage

---

## mapSourceRect

```
public java.awt.Rectangle mapSourceRect(java.awt.Rectangle sourceRect,  
                                          int sourceIndex)
```

Throws an IllegalArgumentException since the image has no image sources.

**Parameters:**

sourceRect - ignored.

sourceIndex - ignored.

**Throws:**

java.lang.IllegalArgumentException - since the image has no sources.

**Overrides:**

mapSourceRect in class OpImage

---

## mapDestRect

```
public java.awt.Rectangle mapDestRect(java.awt.Rectangle destRect,  
                                       int sourceIndex)
```

Throws an IllegalArgumentException since the image has no image sources.

**Parameters:**

destRect - ignored.

sourceIndex - ignored.

**Throws:**

java.lang.IllegalArgumentException - since the image has no sources.

**Overrides:**

mapDestRect in class OpImage

---

## javax.media.jai Class StatisticsOpImage

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|   |
|   +-- javax.media.jai.OpImage
|       |
|       +-- javax.media.jai.StatisticsOpImage
```

---

public abstract class **StatisticsOpImage**  
extends OpImage

An abstract base class for image operators that compute statistics on a given region of an image, and with a given sampling rate. StatisticsOpImage simply passes pixels through unchanged from its parent image. However, the desired statistics are computed on demand and made available as a property or set of properties on the image.

All instances of StatisticsOpImage make use of a region of interest, specified as a ROI object. Additionally, they may perform spatial subsampling of the region of interest according to xPeriod and yPeriod parameters that may vary from 1 (sample every pixel of the region of interest) upwards. This allows the speed and quality of statistics gathering to be traded off against one another.

Subclasses provide implementations of the getStatisticsNames, createStatistics, and accumulateStatistics methods.

### See Also:

OpImage

---

## Field Detail

### roi

protected ROI **roi**

The region of interest over which to compute the statistics.

---

### xStart

protected int **xStart**

The X coordinate of the initial sample.

---

### yStart

protected int **yStart**

The Y coordinate of the initial sample.

---

### xPeriod

protected int **xPeriod**

The horizontal sampling rate.

---

### yPeriod

protected int **yPeriod**

The vertical sampling rate.

---

### maxWidth

protected int **maxWidth**

The largest allowable width of the source argument to accumulateStatistics. Subclasses may set this value by means of the corresponding constructor argument.

---

---

## maxHeight

protected int **maxHeight**

The largest allowable height of the source argument to accumulateStatistics. Subclasses may set this value by means of the corresponding constructor argument.

---

## properties

protected java.util.Hashtable **properties**

A Hashtable containing all the properties generated, hashed by property names.

## Constructor Detail

### StatisticsOpImage

```
public StatisticsOpImage(java.awt.image.RenderedImage source,
                        ROI roi,
                        int xStart,
                        int yStart,
                        int xPeriod,
                        int yPeriod,
                        int maxWidth,
                        int maxHeight)
```

Constructs a StatisticsOpImage. The image layout is copied from the source image.

**Parameters:**

source - A RenderedImage.  
roi - The region of interest, as a ROI.  
xStart - The initial X sample coordinate.  
yStart - The initial Y sample coordinate.  
xPeriod - The X sampling rate.  
yPeriod - The Y sampling rate.  
maxWidth - The largest allowed width for processing.  
maxHeight - The largest allowed height for processing.

## Method Detail

### layoutHelper

```
private static ImageLayout layoutHelper(java.awt.image.RenderedImage source)
```

---

### mapSourceRect

```
public java.awt.Rectangle mapSourceRect(java.awt.Rectangle sourceRect,
                                          int sourceIndex)
```

Maps the source rectangle into destination space unchanged.

**Parameters:**

sourceRect - the Rectangle in source coordinates.  
sourceIndex - the index of the source image.

**Returns:**

a Rectangle indicating the required source region.

**Throws:**

java.lang.IllegalArgumentException - if sourceIndex is negative or greater than the index of the last source.  
NullPointerException - if sourceRect is null.

**Overrides:**

mapSourceRect in class OpImage

---

### mapDestRect

```
public java.awt.Rectangle mapDestRect(java.awt.Rectangle destRect,
                                         int sourceIndex)
```

Maps the destination rectangle into source space unchanged.

**Parameters:**

destRect - the Rectangle in destination coordinates.  
sourceIndex - the index of the source image.

**Returns:**

a `Rectangle` indicating the valid destination region.

**Throws:**

`java.lang.IllegalArgumentException` - if `sourceIndex` is negative or greater than the index of the last source.  
`NullPointerException` - if `destRect` is null.

**Overrides:**

`mapDestRect` in class `OpImage`

---

**getTile**

```
public java.awt.image.Raster getTile(int tileX,  
                                     int tileY)
```

Returns a tile for reading. The tile request is simply forwarded to the source image.

**Parameters:**

`tileX` - the X index of the tile.

`tileY` - the Y index of the tile.

**Returns:**

the tile as a `Raster`.

**Overrides:**

`getTile` in class `OpImage`

---

**getTiles**

```
public java.awt.image.Raster[] getTiles(java.awt.Point[] tileIndices)
```

Returns a list of tiles. The request is simply forwarded to the source image.

**Parameters:**

`tileIndices` - The indices of the tiles requested.

**Overrides:**

`getTiles` in class `OpImage`

---

**tileIntersectsROI**

```
private final boolean tileIntersectsROI(int tileX,  
                                         int tileY)
```

---

**getProperty**

```
public java.lang.Object getProperty(java.lang.String name)
```

Returns one of the available statistics as a property. If the property name is not recognized, `java.awt.Image.UndefinedProperty` will be returned.

**Overrides:**

`getProperty` in class `PlanarImage`

---

**getPropertyNames**

```
public java.lang.String[] getPropertyNames()
```

Returns a list of property names that are recognized by this image.

**Returns:**

an array of `Strings` containing valid property names.

**Overrides:**

`getPropertyNames` in class `PlanarImage`

---

**getStatisticsNames**

```
protected abstract java.lang.String[] getStatisticsNames()
```

Returns a list of names of statistics understood by this class.

---

## **createStatistics**

protected abstract java.lang.Object **createStatistics**(java.lang.String name)

Returns an object that will be used to gather the named statistic.

### **Parameters:**

name - the name of the statistic to be gathered.

---

## **accumulateStatistics**

protected abstract void **accumulateStatistics**(java.lang.String name,  
java.awt.image.Raster source,  
java.lang.Object stats)

Accumulates statistics on the specified region into the previously created statistics object. The region of interest and X and Y sampling rate should be respected.

### **Parameters:**

name - the name of the statistic to be gathered.

source - a Raster containing source pixels. The dimensions of the Raster will not exceed maxWidth x maxHeight.

stats - a statistics object generated by a previous call to createStatistics.

```

---

## javax.media.jai Interface TileCache

---

public abstract interface **TileCache**

A class implementing a caching mechanism for image tiles.

TileCache provides a central place for OpImages to cache tiles they have computed. The tile cache is created with a given tileCapacity measured in Rasters and a given memoryCapacity measured in bytes.

---

### Method Detail

#### add

```
public void add(java.awt.image.RenderedImage owner,
                int tileX,
                int tileY,
                java.awt.image.Raster data)
```

Adds a tile to the cache.

**Parameters:**

owner - The RenderedImage that the tile belongs to.  
tileX - The X index of the tile in the owner's tile grid.  
tileY - The Y index of the tile in the owner's tile grid.  
data - A Raster containing the tile data.

---

#### remove

```
public void remove(java.awt.image.RenderedImage owner,
                   int tileX,
                   int tileY)
```

Advises the cache that a tile is no longer needed. It is legal to implement this method as a no-op.

**Parameters:**

owner - The RenderedImage that the tile belongs to.  
tileX - The X index of the tile in the owner's tile grid.  
tileY - The Y index of the tile in the owner's tile grid.

---

#### getTile

```
public java.awt.image.Raster getTile(java.awt.image.RenderedImage owner,
                                      int tileX,
                                      int tileY)
```

Retrieves a tile. Returns null if the tile is not present in the cache.

**Parameters:**

owner - The RenderedImage that the tile belongs to.  
tileX - The X index of the tile in the owner's tile grid.  
tileY - The Y index of the tile in the owner's tile grid.

---

#### removeTiles

```
public void removeTiles(java.awt.image.RenderedImage owner)
```

Advises the cache that all tiles associated with a given image are no longer needed. It is legal to implement this method as a no-op.

**Parameters:**

owner - The RenderedImage owner of the tiles to be removed.

---

#### flush

```
public void flush()
```

Advises the cache that all of its tiles may be discarded. It is legal to implement this method as a no-op.

---

### **setTileCapacity**

```
public void setTileCapacity(int tileCapacity)
```

Sets the tile capacity to a desired number of tiles. If the capacity is smaller than the current capacity, tiles are flushed from the cache.

**Parameters:**

tileCapacity - The new capacity, in tiles.

---

### **getTileCapacity**

```
public int getTileCapacity()
```

Returns the tile capacity in tiles.

---

### **setMemoryCapacity**

```
public void setMemoryCapacity(long memoryCapacity)
```

Sets the memory capacity to a desired number of bytes. If the memory capacity is smaller than the amount of memory currently used by the cache, tiles are flushed until the TileCache's memory usage is less than memoryCapacity.

**Parameters:**

memoryCapacity - The new capacity, in bytes.

---

### **getMemoryCapacity**

```
public long getMemoryCapacity()
```

Returns the memory capacity in bytes.

---

## javax.media.jai Class TileCopy

java.lang.Object  
|  
+-- javax.media.jai.TileCopy

---

final class **TileCopy**  
extends java.lang.Object  
A (Raster, X, Y) tuple.

---

### Field Detail

#### tile

java.awt.image.Raster **tile**  
The tile's Raster data.

---

#### tileX

int **tileX**  
The tile's column within the image tile grid.

---

#### tileY

int **tileY**  
The tile's row within the image tile grid.

---

### Constructor Detail

#### TileCopy

**TileCopy**(java.awt.image.Raster tile,  
int tileX,  
int tileY)

Constructs a TileCopy object given the tile's Raster data and its location in the tile grid.

**Parameters:**

tile - the Raster containing the tile's data.  
tileX - the tile's X position in the tile grid.  
tileY - the tile's Y position in the tile grid.

---

## javax.media.jai Interface **TileScheduler**

---

public abstract interface **TileScheduler**

A class implementing a mechanism for scheduling tile calculation. In various implementations tile computation may make use of multithreading and multiple simultaneous network connections for improved performance.

---

### Method Detail

#### **scheduleTile**

```
public java.awt.image.Raster scheduleTile(OpImage target,  
                                           int tileX,  
                                           int tileY)
```

Schedules a tile for computation. Called by `OpImage.getTile()`. After performing a dependency analysis, this method makes `OpImage.computeTile()` calls for source tiles needed to calculate the ultimate destination tile.

**Parameters:**

`target` - An `OpImage` whose tile is to be computed.  
`tileX` - The X index of the tile to be computed.  
`tileY` - The Y index of the tile to be computed.

**Returns:**

A `Raster` containing the contents of the tile.

---

#### **scheduleTiles**

```
public java.awt.image.Raster[] scheduleTiles(OpImage target,  
                                              java.awt.Point[] tileIndices)
```

Schedules a list of tiles for computation. Called by `OpImage.getTiles`. After performing a dependency analysis, this method makes `OpImage.computeTile()` calls for source tiles needed to calculate the ultimate destination tile.

**Parameters:**

`target` - The `OpImage` to schedule tiles from.  
`tileIndices` - A list of `tileIndices` indicating which tiles to schedule for computation.

**Returns:**

An array of `Raster` containing a computed raster for every `tileIndex` passed in.

---

#### **prefetchTiles**

```
public void prefetchTiles(PlanarImage target,  
                          java.awt.Point[] tileIndices)
```

Hints to the `TileScheduler` that the given tiles from the given `PlanarImage` might be needed in the near future. Some `TileScheduler` implementations will spawn a low priority thread to compute the tiles while others may ignore the hint.

**Parameters:**

`target` - The `OpImage` to prefetch tiles from.  
`tileIndices` - A list of `tileIndices` indicating which tiles to prefetch.

---

## javax.media.jai Class TiledImage

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|   |
|   +-- javax.media.jai.TiledImage
```

---

public class **TiledImage**  
extends PlanarImage  
implements java.awt.image.WritableRenderedImage  
A concrete implementation of WritableRenderedImage.

TiledImage is the main class for writable images in JAI. TiledImage provides a straightforward implementation of the WritableRenderedImage interface, taking advantage of that interface's ability to describe images with multiple tiles. The tiles of a WritableRenderedImage must share a SampleModel, which determines their width, height, and pixel format. The tiles form a regular grid, which may occupy any rectangular region of the plane. Tile pixels that exceed the image's stated bounds have undefined values.

The contents of a TiledImage are defined by a single PlanarImage source provided by means of one of the set() methods. The set() methods provide a way to selectively overwrite a portion of a TiledImage, possibly using a soft-edged mask.

TiledImage also supports direct manipulation of pixels by means of the getWritableTile() method. This method returns a WritableRaster that can be modified directly. Such changes become visible to readers according to the regular thread synchronization rules of the Java virtual machine; JAI makes no additional guarantees. When a writer is finished modifying a tile, it should call releaseWritableTile(). A shortcut is to call setData(), which copies a rectangular region from a supplied Raster directly into the TiledImage.

A final way to modify the contents of a TiledImage is through calls to createGraphics(). This returns a Graphics2D object that can be used to draw line art, text, and images in the usual AWT manner.

A TiledImage does not attempt to maintain synchronous state on its own. That task is left to SnapshotImage. If a synchronous (unchangeable) view of a TiledImage is desired, its createSnapshot() method must be used. Otherwise, changes due to calls to set() or direct writing of tiles by objects that call getWritableTile() will be visible.

TiledImage does not actually cause its tiles to be computed until their contents are demanded. Once a tile has been computed, its contents may be discarded if it can be determined that it can be recomputed identically from the source. The lockTile() method forces a tile to be computed and maintained for the lifetime of the TiledImage.

---

## Field Detail

### tilesX

protected int **tilesX**

The number of tiles in the X direction.

---

### tilesY

protected int **tilesY**

The number of tiles in the Y direction.

---

### minTileX

protected int **minTileX**

The index of the leftmost column of tiles.

---

### minTileY

protected int **minTileY**

The index of the uppermost row of tiles.

---

## tiles

protected java.awt.image.WritableRaster[] **tiles**  
The tile array.

---

## writers

protected int[][] **writers**  
The number of writers of each tile; -1 indicates a locked tile.

---

## tileObservers

protected java.util.Vector **tileObservers**  
The current set of TileObservers.

---

## src

protected PlanarImage **src**  
The source image for uncomputed tiles.

---

## imageBounds

private java.awt.Rectangle **imageBounds**

---

## parent

private TiledImage **parent**

---

## ancestorSampleModel

private java.awt.image.SampleModel **ancestorSampleModel**

---

## overlapBounds

private java.awt.Rectangle **overlapBounds**

---

<h2>Constructor Detail</h2>
-----------------------------

## TiledImage

```
public TiledImage(int minX,
                  int minY,
                  int width,
                  int height,
                  int tileGridXOffset,
                  int tileGridYOffset,
                  java.awt.image.SampleModel sampleModel,
                  java.awt.image.ColorModel colorModel)
```

Constructs a `TiledImage` with a given layout, `SampleModel`, and `ColorModel`.

**Parameters:**

`minX` - The X coordinate of the upper-left pixel  
`minY` - The Y coordinate of the upper-left pixel.  
`width` - The width of the image.  
`height` - The height of the image.  
`tileGridXOffset` - The X coordinate of the upper-left pixel of tile (0, 0).  
`tileGridYOffset` - The Y coordinate of the upper-left pixel of tile (0, 0).  
`sampleModel` - A `SampleModel` with which to be compatible.  
`colorModel` - A `ColorModel` to associate with the image.

---

## TiledImage

```
private TiledImage(TiledImage parent,
                    int minX,
                    int minY,
                    int width,
                    int height,
                    int tileGridXOffset,
                    int tileGridYOffset,
                    java.awt.image.SampleModel sampleModel,
                    java.awt.image.ColorModel colorModel)
```

---

## TiledImage

```
public TiledImage(java.awt.Point origin,
                  java.awt.image.SampleModel sampleModel,
                  int tileWidth,
                  int tileHeight)
```

Constructs a `TiledImage` with a `SampleModel` that is compatible with a given `SampleModel`, and given tile dimensions. The width and height are taken from the `SampleModel`, and the image begins at a specified point.

**Parameters:**

`origin` - A `Point` indicating the image's upper left corner.  
`sampleModel` - A `SampleModel` with which to be compatible.  
`tileWidth` - The desired tile width.  
`tileHeight` - The desired tile height.

---

## TiledImage

```
public TiledImage(java.awt.image.SampleModel sampleModel,
                  int tileWidth,
                  int tileHeight)
```

Constructs a `TiledImage` starting at the global coordinate origin.

**Parameters:**

`sampleModel` - A `SampleModel` with which to be compatible.  
`tileWidth` - The desired tile width.  
`tileHeight` - The desired tile height.

---

## Method Detail

### initTileGrid

```
private void initTileGrid(TiledImage parent)
```

---

### createInterleaved

```
public static TiledImage createInterleaved(int minX,
                                             int minY,
                                             int width,
                                             int height,
                                             int numBands,
                                             int dataType,
                                             int tileWidth,
                                             int tileHeight,
                                             int[] bandOffsets)
```

Returns a `TiledImage` making use of an interleaved `SampleModel` with a given layout, number of bands, and data type.

**Parameters:**

`minX` - The X coordinate of the upper-left pixel  
`minY` - The Y coordinate of the upper-left pixel.  
`width` - The width of the image.  
`height` - The height of the image.  
`numBands` - The number of bands in the image.  
`dataType` - The data type, from among the constants `DataBuffer.TYPE_*`.  
`tileWidth` - The tile width.  
`tileHeight` - The tile height.  
`bandOffsets` - An array of non-duplicated integers between 0 and `numBands - 1` of length `numBands` indicating the relative offset of each band.

---

## createBanded

```
public static TiledImage createBanded(int minX,  
                                     int minY,  
                                     int width,  
                                     int height,  
                                     int dataType,  
                                     int tileWidth,  
                                     int tileHeight,  
                                     int[] bankIndices,  
                                     int[] bandOffsets)
```

Returns a `TiledImage` making use of an banded `SampleModel` with a given layout, number of bands, and data type.

**Parameters:**

`minX` - The X coordinate of the upper-left pixel  
`minY` - The Y coordinate of the upper-left pixel.  
`width` - The width of the image.  
`height` - The height of the image.  
`dataType` - The data type, from among the constants `DataBuffer.TYPE_*`.  
`tileWidth` - The tile width.  
`tileHeight` - The tile height.  
`bankIndices` - An array of ints indicating the index of the bank to use for each band. Bank indices may be duplicated.  
`bandOffsets` - An array of integers indicating the starting offset of each band within its bank. Bands stored in the same bank must have sufficiently different offsets so as not to overlap.

---

## overlayPixels

```
private void overlayPixels(java.awt.image.WritableRaster tile,  
                           java.awt.image.RenderedImage im,  
                           java.awt.Rectangle rect)
```

Overlays a rectangular area of pixels from an image onto a tile.

**Parameters:**

`tile` -  
`im` -  
`rect` -

---

## overlayPixels

```
private void overlayPixels(java.awt.image.WritableRaster tile,  
                           java.awt.image.RenderedImage im,  
                           java.awt.geom.Area a)
```

Overlays a set of pixels described by an `Area` from an image onto a tile.

**Parameters:**

`tile` -  
`im` -  
`a` -

---

## overlayPixels

```
private void overlayPixels(java.awt.image.WritableRaster tile,
                           java.awt.image.RenderedImage im,
                           java.awt.Rectangle rect,
                           int[][] bitmask)
```

Overlays a set of pixels described by a bitmask onto a tile.

---

## set

```
public void set(java.awt.image.RenderedImage im)
```

Overlays a given `RenderedImage` on top of the current contents of the `TiledImage`. The source image must have a `SampleModel` compatible with that of this image. If the source image does not overlap this image then invoking this method will have no effect.

**Parameters:**

im - A `RenderedImage` source to overlay.

---

## set

```
public void set(java.awt.image.RenderedImage im,
                ROI roi)
```

Overlays a given `RenderedImage` on top of the current contents of the `TiledImage`. The source image must have a `SampleModel` compatible with that of this image. If the source image and the region of interest do not both overlap this image then invoking this method will have no effect.

**Parameters:**

im - A `RenderedImage` source to overlay.

roi - The region of interest.

---

## getGraphics

```
public java.awt.Graphics getGraphics()
```

Creates a `Graphics` object that can be used to paint text and graphics onto the `TiledImage`. The `TiledImage` must be of integral data type or an `UnsupportedOperationException` will be thrown.

**Overrides:**

`getGraphics` in class `PlanarImage`

---

## createGraphics

```
public java.awt.Graphics2D createGraphics()
```

Creates a `Graphics2D` object that can be used to paint text and graphics onto the `TiledImage`. The `TiledImage` must be of integral data type or an `UnsupportedOperationException` will be thrown.

---

## getSubImage

```
public TiledImage getSubImage(int x,
                              int y,
                              int w,
                              int h,
                              int[] bandSelect)
```

Returns a `TiledImage` that shares the tile `Rasters` of this image. The returned image occupies a sub-area of the parent image, and possesses a possibly permuted subset of the parent's bands. The two images share a common coordinate system.

The image bounds are clipped against the bounds of the parent image.

**Parameters:**

x - the minimum X coordinate of the subimage.

y - the minimum Y coordinate of the subimage.

w - the width of the subimage.

h - the height of the subimage.

bandSelect - an array of band indices; if null, all bands are selected.

---

## getSubImage

```
public TiledImage getSubImage(int x,  
                               int y,  
                               int w,  
                               int h)
```

Returns a `TiledImage` that shares the tile Rasters of this image. The returned image occupies a subarea of the parent image. The two images share a common coordinate system.

The image bounds are clipped against the bounds of the parent image.

**Parameters:**

x - the minimum X coordinate of the subimage.  
y - the minimum Y coordinate of the subimage.  
w - the width of the subimage.  
h - the height of the subimage.

---

## getSubImage

```
public TiledImage getSubImage(int[] bandSelect)
```

Returns a `TiledImage` that shares the tile Rasters of this image. The returned image occupies the same area as the parent image, and possesses a possibly permuted subset of the parent's bands.

**Parameters:**

bandSelect - an array of band indices.

---

## createTile

```
private void createTile(int tileX,  
                        int tileY)
```

Forces the requested tile to be computed if has not already been so and if a source is available.

---

## getTile

```
public java.awt.image.Raster getTile(int tileX,  
                                       int tileY)
```

Retrieves a particular tile from the image for reading only. The tile will be computed if it hasn't been previously. Any attempt to write to the tile will produce undefined results.

**Parameters:**

tileX - the X index of the tile.  
tileY - the Y index of the tile.

**Overrides:**

getTile in class `PlanarImage`

---

## getWritableTile

```
public java.awt.image.WritableRaster getWritableTile(int tileX,  
                                                       int tileY)
```

Retrieves a particular tile from the image for reading and writing. If the tile is locked, null will be returned. Otherwise, the tile will be computed if it hasn't been previously. Writes to the tile will become visible to readers of this image as they occur.

**Specified by:**

getWritableTile in interface `java.awt.image.WritableRenderedImage`

**Parameters:**

tileX - the X index of the tile.  
tileY - the Y index of the tile.

**Returns:**

The requested tile or null if the tile is locked.

---

## releaseWritableTile

```
public void releaseWritableTile(int tileX,  
                                 int tileY)
```

Indicates that a writer is done updating a tile. The effects of attempting to release a tile that has not been grabbed, or releasing a tile more than once are undefined.

**Specified by:**

releaseWritableTile in interface `java.awt.image.WritableRenderedImage`

**Parameters:**

tileX - the X index of the tile.  
tileY - the Y index of the tile.

---

## lockTile

```
protected boolean lockTile(int tileX,  
                           int tileY)
```

Forces a tile to be computed, and its contents stored indefinitely. A tile may not be locked if it is currently writable. This method should only be used within JAI, in order to optimize memory allocation.

**Parameters:**

tileX - the X index of the tile.  
tileY - the Y index of the tile.

**Returns:**

Whether the tile was successfully locked.

---

## isTileLocked

```
protected boolean isTileLocked(int tileX,  
                               int tileY)
```

Returns true if a tile is locked.

**Parameters:**

tileX - the X index of the tile.  
tileY - the Y index of the tile.

**Returns:**

Whether the tile is locked.

---

## setData

```
public void setData(java.awt.image.Raster r)
```

Sets a region of a TiledImage to be a copy of a supplied Raster. The Raster's coordinate system is used to position it within the image. The computation of all overlapping tiles will be forced prior to modification of the data of the affected area.

**Specified by:**

setData in interface java.awt.image.WritableRenderedImage

**Parameters:**

r - a Raster containing pixels to be copied into the TiledImage.

---

## setData

```
public void setData(java.awt.image.Raster r,  
                    ROI roi)
```

Sets a region of a TiledImage to be a copy of a supplied Raster. The Raster's coordinate system is used to position it within the image. The computation of all overlapping tiles will be forced prior to modification of the data of the affected area.

**Parameters:**

r - a Raster containing pixels to be copied into the TiledImage.  
roi - The region of interest.

---

## addTileObserver

```
public void addTileObserver(java.awt.image.TileObserver observer)
```

Informs this TiledImage that another object is interested in being notified whenever any tile becomes writable or ceases to be writable. A tile becomes writable when it is not currently writable and getWritableTile() is called. A tile ceases to be writable when releaseTile() is called and the number of calls to getWritableTile() and releaseWritableTile() are identical.

It is the responsibility of the TiledImage to inform all registered TileObserver objects of such changes in tile writability before the writer has a chance to make any modifications.

**Specified by:**

addTileObserver in interface java.awt.image.WritableRenderedImage

**Parameters:**

observer - An object implementing the TileObserver interface.

---

## removeTileObserver

```
public void removeTileObserver(java.awt.image.TileObserver observer)
```

Informs this `TiledImage` that a particular `TileObserver` no longer wishes to receive updates on tile writability status. The result of attempting to remove a listener that is not registered is undefined.

**Specified by:**

`removeTileObserver` in interface `java.awt.image.WritableRenderedImage`

**Parameters:**

`observer` - An object implementing the `TileObserver` interface.

---

## getWritableTileIndices

```
public java.awt.Point[] getWritableTileIndices()
```

Returns a list of tiles that are currently held by one or more writers.

**Specified by:**

`getWritableTileIndices` in interface `java.awt.image.WritableRenderedImage`

**Returns:**

An array of `Points` representing tile indices.

---

## hasTileWriters

```
public boolean hasTileWriters()
```

Returns `true` if any tile is being held by a writer, `false` otherwise. This provides a quick way to check whether it is necessary to make copies of tiles -- if there are no writers, it is safe to use the tiles directly, while registering to learn of future writers.

**Specified by:**

`hasTileWriters` in interface `java.awt.image.WritableRenderedImage`

---

## isTileWritable

```
public boolean isTileWritable(int tileX,  
                               int tileY)
```

Returns `true` if a tile has writers.

**Specified by:**

`isTileWritable` in interface `java.awt.image.WritableRenderedImage`

**Parameters:**

`tileX` - the X index of the tile.

`tileY` - the Y index of the tile.

---

## setSample

```
public void setSample(int x,  
                      int y,  
                      int b,  
                      int s)
```

Sets a sample of a pixel to a given value.

**Parameters:**

`x` - The X coordinate of the pixel.

`y` - The Y coordinate of the pixel.

`b` - The band of the sample within the pixel.

`s` - The value to which to set the sample.

---

## getSample

```
public int getSample(int x,  
                     int y,  
                     int b)
```

Returns the value of a given sample of a pixel as an `int`.

**Parameters:**

`x` - The X coordinate of the pixel.

`y` - The Y coordinate of the pixel.

`b` - The band of the sample within the pixel.

---

## setSample

```
public void setSample(int x,  
                     int y,  
                     int b,  
                     float s)
```

Sets a sample of a pixel to a given float value.

**Parameters:**

- x - The X coordinate of the pixel.
  - y - The Y coordinate of the pixel.
  - b - The band of the sample within the pixel.
  - s - The value to which to set the sample.
- 

## getSampleFloat

```
public float getSampleFloat(int x,  
                           int y,  
                           int b)
```

Returns the value of a given sample of a pixel as a float.

**Parameters:**

- x - The X coordinate of the pixel.
  - y - The Y coordinate of the pixel.
  - b - The band of the sample within the pixel.
- 

## setSample

```
public void setSample(int x,  
                     int y,  
                     int b,  
                     double s)
```

Sets a sample of a pixel to a given double value.

**Parameters:**

- x - The X coordinate of the pixel.
  - y - The Y coordinate of the pixel.
  - b - The band of the sample within the pixel.
  - s - The value to which to set the sample.
- 

## getSampleDouble

```
public double getSampleDouble(int x,  
                              int y,  
                              int b)
```

Returns the value of a given sample of a pixel as a double.

**Parameters:**

- x - The X coordinate of the pixel.
- y - The Y coordinate of the pixel.
- b - The band of the sample within the pixel.

---

## javax.media.jai Class TiledImageGraphics

```
java.lang.Object
|
+-- java.awt.Graphics
|   |
|   +-- java.awt.Graphics2D
|       |
|       +-- javax.media.jai.TiledImageGraphics
```

---

class **TiledImageGraphics**  
extends java.awt.Graphics2D

A concrete (i.e., non-abstract) class implementing all the methods of Graphics2D (and thus of Graphics) with a TiledImage as the implicit drawing canvas. The actual implementation will use Java2D to do most of the work by packaging up the image tiles in a form that Java2D can understand.

Since the public methods of this class all derive from Graphics2D, they are not commented individually.

The ColorModel for the canvas will be that of the associated TiledImage unless that ColorModel is null. If the TiledImage ColorModel is null, an attempt will first be made to deduce the ColorModel from the SampleModel of the TiledImage using the createColorModel() method of PlanarImage. If the ColorModel is still null, the default RGB ColorModel returned by the getRGBdefault() method of ColorModel will be used if the TiledImage has a compatible SampleModel. If no acceptable ColorModel can be derived an UnsupportedOperationException will be thrown.

## Constructor Detail

### TiledImageGraphics

```
public TiledImageGraphics(TiledImage im)
```

Construct a `TiledImageGraphics` object that draws onto a particular `TiledImage`. The `TiledImage` parameter must be of integral data type or an `UnsupportedOperationException` will be thrown. Likewise, if no appropriate `ColorModel` can be derived an `UnsupportedOperationException` will be thrown.

**Parameters:**

im - The `TiledImage` which will serve as the graphics canvas.

**Throws:**

`UnsupportedOperationException` - if no appropriate `ColorModel` can be derived.

## Method Detail

### getBoundingBox

```
private static final java.awt.Rectangle getBoundingBox(int[] xPoints,  
                                                         int[] yPoints,  
                                                         int nPoints)
```

Determine the bounding box of the points represented by the supplied arrays of X and Y coordinates.

**Parameters:**

xPoints - An array of x points.

yPoints - An array of y points.

nPoints - The total number of points.

### copyState

```
private void copyState(java.awt.Graphics2D g2d)
```

Copy the graphics state of the current object to a `Graphics2D` object.

**Parameters:**

g2d - The target `Graphics2D` object.

### getBogusGraphics2D

```
private java.awt.Graphics2D getBogusGraphics2D(boolean shouldCopyState)
```

Creates a bogus `Graphics2D` object to be used to retrieve information dependent on system aspects which are image-independent.

The `dispose()` method of the `Graphics2D` object returned should be called to free the associated resources as\ soon as possible.

**Parameters:**

shouldCopyState - Whether the state of the returned `Graphics2D` should be initialized to that of the current `TiledImageGraphics` object.

**Returns:**

A `Graphics2D` object.

## getColorModel

```
private static java.awt.image.ColorModel getColorModel(TiledImage ti)
```

Derive an appropriate ColorModel for use with the underlying BufferedImage canvas. If an appropriate ColorModel cannot be derived an UnsupportedOperationException will be thrown.

**Returns:**

An appropriate ColorModel.

**Throws:**

UnsupportedOperationException - if no appropriate ColorModel can be derived.

---

## doGraphicsOp

```
private boolean doGraphicsOp(int x,  
                              int y,  
                              int width,  
                              int height,  
                              java.lang.String name,  
                              java.lang.Class[] argTypes,  
                              java.lang.Object[] args)
```

Effect a graphics operation on the TiledImage by creating a BufferedImage for each tile in the affected region and using the corresponding Graphics2D to perform the equivalent operation on the tile.

**Parameters:**

x - The x coordinate of the upper left corner.

y - The y coordinate of the upper left corner.

width - The width of the region.

height - The height of the region.

argTypes - An array of the Classes of the arguments of the specified operation.

args - The arguments of the operation as an array of Objects.

---

## doGraphicsOp

```
private boolean doGraphicsOp(java.awt.Shape s,  
                              java.lang.String name,  
                              java.lang.Class[] argTypes,  
                              java.lang.Object[] args)
```

Effect a graphics operation on the TiledImage by creating a BufferedImage for each tile in the affected region and using the corresponding Graphics2D to perform the equivalent operation on the tile.

**Parameters:**

s - The encompassing Shape.

argTypes - An array of the Classes of the arguments of the specified operation.

args - The arguments of the operation as an array of Objects.

---

## create

```
public java.awt.Graphics create()
```

**Overrides:**

create in class java.awt.Graphics

---

## getColor

```
public java.awt.Color getColor()
```

**Overrides:**

getColor in class java.awt.Graphics

---

## setColor

```
public void setColor(java.awt.Color c)
```

**Overrides:**

setColor in class java.awt.Graphics

---

## setPaintMode

public void **setPaintMode**()

### Overrides:

setPaintMode in class java.awt.Graphics

---

## setXORMode

public void **setXORMode**(java.awt.Color c1)

### Overrides:

setXORMode in class java.awt.Graphics

---

## getFont

public java.awt.Font **getFont**()

### Overrides:

getFont in class java.awt.Graphics

---

## setFont

public void **setFont**(java.awt.Font font)

### Overrides:

setFont in class java.awt.Graphics

---

## getFontMetrics

public java.awt.FontMetrics **getFontMetrics**(java.awt.Font f)

### Overrides:

getFontMetrics in class java.awt.Graphics

---

## getClipBounds

public java.awt.Rectangle **getClipBounds**()

### Overrides:

getClipBounds in class java.awt.Graphics

---

## clipRect

```
public void clipRect(int x,  
                     int y,  
                     int width,  
                     int height)
```

### Overrides:

clipRect in class java.awt.Graphics

---

## setClip

```
public void setClip(int x,  
                   int y,  
                   int width,  
                   int height)
```

### Overrides:

setClip in class java.awt.Graphics

---

## getClip

public java.awt.Shape **getClip**()

### Overrides:

getClip in class java.awt.Graphics

---

## setClip

```
public void setClip(java.awt.Shape clip)
```

### Overrides:

setClip in class java.awt.Graphics

---

## copyArea

```
public void copyArea(int x,  
                    int y,  
                    int width,  
                    int height,  
                    int dx,  
                    int dy)
```

### Overrides:

copyArea in class java.awt.Graphics

---

## drawLine

```
public void drawLine(int x1,  
                    int y1,  
                    int x2,  
                    int y2)
```

### Overrides:

drawLine in class java.awt.Graphics

---

## fillRect

```
public void fillRect(int x,  
                    int y,  
                    int width,  
                    int height)
```

### Overrides:

fillRect in class java.awt.Graphics

---

## clearRect

```
public void clearRect(int x,  
                    int y,  
                    int width,  
                    int height)
```

### Overrides:

clearRect in class java.awt.Graphics

---

## drawRoundRect

```
public void drawRoundRect(int x,  
                        int y,  
                        int width,  
                        int height,  
                        int arcWidth,  
                        int arcHeight)
```

### Overrides:

drawRoundRect in class java.awt.Graphics

---

## fillRoundRect

```
public void fillRoundRect(int x,  
                        int y,  
                        int width,  
                        int height,  
                        int arcWidth,  
                        int arcHeight)
```

**Overrides:**

fillRoundRect in class java.awt.Graphics

---

**draw3DRect**

```
public void draw3DRect(int x,  
                      int y,  
                      int width,  
                      int height,  
                      boolean raised)
```

**Overrides:**

draw3DRect in class java.awt.Graphics2D

---

**fill3DRect**

```
public void fill3DRect(int x,  
                      int y,  
                      int width,  
                      int height,  
                      boolean raised)
```

**Overrides:**

fill3DRect in class java.awt.Graphics2D

---

**drawOval**

```
public void drawOval(int x,  
                    int y,  
                    int width,  
                    int height)
```

**Overrides:**

drawOval in class java.awt.Graphics

---

**fillOval**

```
public void fillOval(int x,  
                    int y,  
                    int width,  
                    int height)
```

**Overrides:**

fillOval in class java.awt.Graphics

---

**drawArc**

```
public void drawArc(int x,  
                   int y,  
                   int width,  
                   int height,  
                   int startAngle,  
                   int arcAngle)
```

**Overrides:**

drawArc in class java.awt.Graphics

---

**fillArc**

```
public void fillArc(int x,  
                   int y,  
                   int width,  
                   int height,  
                   int startAngle,  
                   int arcAngle)
```

**Overrides:**

fillArc in class java.awt.Graphics

---

## drawPolyline

```
public void drawPolyline(int[] xPoints,  
                        int[] yPoints,  
                        int nPoints)
```

### Overrides:

drawPolyline in class java.awt.Graphics

---

## drawPolygon

```
public void drawPolygon(int[] xPoints,  
                      int[] yPoints,  
                      int nPoints)
```

### Overrides:

drawPolygon in class java.awt.Graphics

---

## fillPolygon

```
public void fillPolygon(int[] xPoints,  
                      int[] yPoints,  
                      int nPoints)
```

### Overrides:

fillPolygon in class java.awt.Graphics

---

## drawString

```
public void drawString(java.lang.String str,  
                     int x,  
                     int y)
```

### Overrides:

drawString in class java.awt.Graphics2D

---

## drawImage

```
public boolean drawImage(java.awt.Image img,  
                       int x,  
                       int y,  
                       java.awt.image.ImageObserver observer)
```

### Overrides:

drawImage in class java.awt.Graphics

---

## drawRenderedImage

```
public void drawRenderedImage(java.awt.image.RenderedImage im,  
                             java.awt.geom.AffineTransform transform)
```

### Overrides:

drawRenderedImage in class java.awt.Graphics2D

---

## drawRenderableImage

```
public void drawRenderableImage(java.awt.image.renderable.RenderableImage img,  
                               java.awt.geom.AffineTransform xform)
```

### Overrides:

drawRenderableImage in class java.awt.Graphics2D

---

## drawImage

```
public boolean drawImage(java.awt.Image img,  
                       int x,  
                       int y,  
                       int width,  
                       int height,  
                       java.awt.image.ImageObserver observer)
```

**Overrides:**

drawImage in class java.awt.Graphics

---

**drawImage**

```
public boolean drawImage(java.awt.Image img,
                        int x,
                        int y,
                        java.awt.Color bgcolor,
                        java.awt.image.ImageObserver observer)
```

**Overrides:**

drawImage in class java.awt.Graphics

---

**drawImage**

```
public boolean drawImage(java.awt.Image img,
                        int x,
                        int y,
                        int width,
                        int height,
                        java.awt.Color bgcolor,
                        java.awt.image.ImageObserver observer)
```

**Overrides:**

drawImage in class java.awt.Graphics

---

**drawImage**

```
public boolean drawImage(java.awt.Image img,
                        int dx1,
                        int dy1,
                        int dx2,
                        int dy2,
                        int sx1,
                        int sy1,
                        int sx2,
                        int sy2,
                        java.awt.image.ImageObserver observer)
```

**Overrides:**

drawImage in class java.awt.Graphics

---

**drawImage**

```
public boolean drawImage(java.awt.Image img,
                        int dx1,
                        int dy1,
                        int dx2,
                        int dy2,
                        int sx1,
                        int sy1,
                        int sx2,
                        int sy2,
                        java.awt.Color bgcolor,
                        java.awt.image.ImageObserver observer)
```

**Overrides:**

drawImage in class java.awt.Graphics

---

**dispose**

```
public void dispose()
```

**Overrides:**

dispose in class java.awt.Graphics

---

## addRenderingHints

public void **addRenderingHints**(java.util.Map hints)

### Overrides:

addRenderingHints in class java.awt.Graphics2D

---

## draw

public void **draw**(java.awt.Shape s)

### Overrides:

draw in class java.awt.Graphics2D

---

## drawImage

public boolean **drawImage**(java.awt.Image img,  
java.awt.geom.AffineTransform xform,  
java.awt.image.ImageObserver obs)

### Overrides:

drawImage in class java.awt.Graphics2D

---

## drawImage

public void **drawImage**(java.awt.image.BufferedImage img,  
java.awt.image.BufferedImageOp op,  
int x,  
int y)

### Overrides:

drawImage in class java.awt.Graphics2D

---

## drawString

public void **drawString**(java.lang.String s,  
float x,  
float y)

### Overrides:

drawString in class java.awt.Graphics2D

---

## drawString

public void **drawString**(java.text.AttributedString iterator,  
int x,  
int y)

### Overrides:

drawString in class java.awt.Graphics2D

---

## drawString

public void **drawString**(java.text.AttributedString iterator,  
float x,  
float y)

### Overrides:

drawString in class java.awt.Graphics2D

---

## drawGlyphVector

public void **drawGlyphVector**(java.awt.font.GlyphVector g,  
float x,  
float y)

### Overrides:

drawGlyphVector in class java.awt.Graphics2D

---

## **fill**

public void **fill**(java.awt.Shape s)

### **Overrides:**

fill in class java.awt.Graphics2D

---

## **hit**

public boolean **hit**(java.awt.Rectangle rect,  
java.awt.Shape s,  
boolean onStroke)

### **Overrides:**

hit in class java.awt.Graphics2D

---

## **getDeviceConfiguration**

public java.awt.GraphicsConfiguration **getDeviceConfiguration**()

### **Overrides:**

getDeviceConfiguration in class java.awt.Graphics2D

---

## **setComposite**

public void **setComposite**(java.awt.Composite comp)

### **Overrides:**

setComposite in class java.awt.Graphics2D

---

## **setPaint**

public void **setPaint**(java.awt.Paint paint)

### **Overrides:**

setPaint in class java.awt.Graphics2D

---

## **setStroke**

public void **setStroke**(java.awt.Stroke s)

### **Overrides:**

setStroke in class java.awt.Graphics2D

---

## **setRenderingHint**

public void **setRenderingHint**(java.awt.RenderingHints.Key hintKey,  
java.lang.Object hintValue)

### **Overrides:**

setRenderingHint in class java.awt.Graphics2D

---

## **getRenderingHint**

public java.lang.Object **getRenderingHint**(java.awt.RenderingHints.Key hintKey)

### **Overrides:**

getRenderingHint in class java.awt.Graphics2D

---

## **setRenderingHints**

public void **setRenderingHints**(java.util.Map hints)

### **Overrides:**

setRenderingHints in class java.awt.Graphics2D

---

## getRenderingHints

public java.awt.RenderingHints **getRenderingHints**()

### Overrides:

getRenderingHints in class java.awt.Graphics2D

---

## translate

public void **translate**(int x,  
int y)

### Overrides:

translate in class java.awt.Graphics2D

---

## translate

public void **translate**(double x,  
double y)

### Overrides:

translate in class java.awt.Graphics2D

---

## rotate

public void **rotate**(double theta)

### Overrides:

rotate in class java.awt.Graphics2D

---

## rotate

public void **rotate**(double theta,  
double x,  
double y)

### Overrides:

rotate in class java.awt.Graphics2D

---

## scale

public void **scale**(double sx,  
double sy)

### Overrides:

scale in class java.awt.Graphics2D

---

## shear

public void **shear**(double shx,  
double shy)

### Overrides:

shear in class java.awt.Graphics2D

---

## transform

public void **transform**(java.awt.geom.AffineTransform Tx)

### Overrides:

transform in class java.awt.Graphics2D

---

## setTransform

public void **setTransform**(java.awt.geom.AffineTransform Tx)

### Overrides:

setTransform in class java.awt.Graphics2D

---

## **getTransform**

public java.awt.geom.AffineTransform **getTransform**()

### **Overrides:**

getTransform in class java.awt.Graphics2D

---

## **getPaint**

public java.awt.Paint **getPaint**()

### **Overrides:**

getPaint in class java.awt.Graphics2D

---

## **getComposite**

public java.awt.Composite **getComposite**()

### **Overrides:**

getComposite in class java.awt.Graphics2D

---

## **setBackground**

public void **setBackground**(java.awt.Color color)

### **Overrides:**

setBackground in class java.awt.Graphics2D

---

## **getBackground**

public java.awt.Color **getBackground**()

### **Overrides:**

getBackground in class java.awt.Graphics2D

---

## **getStroke**

public java.awt.Stroke **getStroke**()

### **Overrides:**

getStroke in class java.awt.Graphics2D

---

## **clip**

public void **clip**(java.awt.Shape s)

### **Overrides:**

clip in class java.awt.Graphics2D

---

## **getFontRenderContext**

public java.awt.font.FontRenderContext **getFontRenderContext**()

### **Overrides:**

getFontRenderContext in class java.awt.Graphics2D

---

## javax.media.jai Class UntiledOpImage

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|   |
|   +-- javax.media.jai.OpImage
|       |
|       +-- javax.media.jai.UntiledOpImage
```

---

public abstract class **UntiledOpImage**  
extends OpImage

A general class for single-source operations in which the values of all pixels in the source image contribute to the value of each pixel in the destination image.

The output image will have a single tile, regardless of the ImageLayout settings passed to the constructor.

Subclasses should implement the computeImage method which requests computation of the entire image at once.

**See Also:**

OpImage

---

### Field Detail

#### tileDependencies

private java.awt.Point[] **tileDependencies**

The tile dependency array: needs to be computed only once.

---

### Constructor Detail

#### UntiledOpImage

```
public UntiledOpImage(java.awt.image.RenderedImage source,  
                     TileCache cache,  
                     ImageLayout layout)
```

Constructs an UntiledOpImage. The image layout is copied from the source image. The tile grid layout, SampleModel, and ColorModel may optionally be specified by an ImageLayout object. Cobbling will be performed on the source image as needed.

**Parameters:**

source - a RenderedImage.  
cache - a TileCache object to store tiles from this OpImage, or null. If null, a default cache will be used.  
layout - an ImageLayout optionally containing the SampleModel, and ColorModel. The tile grid layout information will be overridden in order to ensure that the image has a single tile.

---

### Method Detail

#### layoutHelper

```
private static ImageLayout layoutHelper(ImageLayout layout,  
                                         java.awt.image.RenderedImage source)
```

Creates the ImageLayout for the image. If the layout parameter is null, create a new ImageLayout using as a fallback equivalent to which the RenderedImage would have. Also, force the tile grid offset to equal the image origin and the tile width and height to be equal to the image width and height, respectively, thereby forcing the image to have a single tile.

**Parameters:**

layout - The ImageLayout to be cloned; may be null.  
source - The RenderedImage the attributes of which are to be used as fallbacks in creating a new ImageLayout.

**Returns:**

The ImageLayout to be used.

---

## mapSourceRect

```
public java.awt.Rectangle mapSourceRect(java.awt.Rectangle sourceRect,  
                                         int sourceIndex)
```

Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**Parameters:**

sourceRect - the Rectangle in source coordinates.  
sourceIndex - the index of the source image.

**Returns:**

a Rectangle indicating the potentially affected destination region, or null if the region is unknown.

**Throws:**

java.lang.IllegalArgumentException - if sourceIndex is negative or greater than the index of the last source.  
NullPointerException - if sourceRect is null.

**Overrides:**

mapSourceRect in class OpImage

---

## mapDestRect

```
public java.awt.Rectangle mapDestRect(java.awt.Rectangle destRect,  
                                       int sourceIndex)
```

Returns a conservative estimate of the region of a specified source that is required in order to compute the pixels of a given destination rectangle.

**Parameters:**

destRect - the Rectangle in destination coordinates.  
sourceIndex - the index of the source image.

**Returns:**

a Rectangle indicating the required source region.

**Throws:**

java.lang.IllegalArgumentException - if sourceIndex is negative or greater than the index of the last source.  
NullPointerException - if destRect is null.

**Overrides:**

mapDestRect in class OpImage

---

## computeTile

```
public java.awt.image.Raster computeTile(int tileX,  
                                           int tileY)
```

Computes a tile. The entire source is cobbled together and computeImage is called to produce the single output tile.

**Parameters:**

tileX - The X index of the tile.  
tileY - The Y index of the tile.

**Overrides:**

computeTile in class OpImage

---

## computeImage

```
protected abstract void computeImage(java.awt.image.Raster source,  
                                       java.awt.image.WritableRaster dest,  
                                       java.awt.Rectangle destRect)
```

Calculate the destination image from the source image.

**Parameters:**

source - The source Raster; should be the whole image.  
dest - The destination WritableRaster; should be the whole image.  
destRect - The destination Rectangle; should equal the destination image bounds.

---

## getTileDependencies

```
public java.awt.Point[] getTileDependencies(int tileX,  
                                             int tileY,  
                                             int sourceIndex)
```

Returns an array of points indicating the tile dependencies which in this case is the set of all tiles in the source image.

**Overrides:**

getTileDependencies in class OpImage

---

## javax.media.jai

### Class Warp

java.lang.Object

|-- javax.media.jai.Warp

#### Direct Known Subclasses:

WarpGrid, WarpPerspective, WarpPolynomial

---

public abstract class **Warp**

extends java.lang.Object

implements java.io.Serializable

A description of an image warp.

The central method of a Warp is `warpSparseRect()`, which returns the source pixel positions for a specified (subdivided) rectangular region of the output.

As in the `Interpolation` class, pixel positions are represented using scaled integer coordinates, yielding subpixel accuracy but still allowing the use of integer arithmetic. The degree of precision is set by means of the `getSubSampleBitsH()` and `getSubSampleBitsV` parameters to the `warpRect()` method.

#### See Also:

`Interpolation`, `WarpAffine`, `WarpGrid`, `WarpPerspective`, `WarpPolynomial`, `WarpQuadratic`, `WarpOpImage`

---

## Constructor Detail

### Warp

protected **Warp**()

Default constructor.

## Method Detail

### warpRect

```
public int[] warpRect(int x,  
                      int y,  
                      int width,  
                      int height,  
                      int subsampleBitsH,  
                      int subsampleBitsV,  
                      int[] destRect)
```

Computes the source subpixel positions for a given rectangular destination region. The destination region is specified using normal integral (full pixel) coordinates. The source positions returned by the method are specified in fixed point, subpixel coordinates using the `subsampleBitsH` and `subsampleBitsV` parameters.

The integral destination rectangle coordinates should be considered pixel indices. The actual real (non-discrete) plane of pixels locates each pixel index at a half-pixel location. For example, destination pixel (0,0) is located at the real location (0.5, 0.5). Thus pixels are considered to have a dimension of (1.0 x 1.0) with their "energy" concentrated in a "delta function" at relative coordinates (0.5, 0.5).

Destination to source mappings must keep this (0.5, 0.5) pixel center in mind when formulating transformation functions. Given integral destination pixel indices as an input, the fractional source location, as calculated by functions `X(xDst,yDst)`, `Y(xDst,yDst)` is given by:

```
Xsrc = X(xDst+0.5, yDst+0.5) - 0.5  
Ysrc = Y(xDst+0.5, yDst+0.5) - 0.5
```

The subtraction of 0.5 in the above formula produces the source pixel indices (in fractional form) needed to implement the various types of interpolation algorithms.

All of the Sun-supplied warp mapping functions perform the above final subtraction, since they have no knowledge of what interpolation algorithm will be used by a `WarpOpImage` implementation.

As a convenience, an implementation is provided for this method that calls `warpSparseRect()`. Subclasses may wish to provide their own implementations for better performance.

#### Parameters:

`x` - The minimum X coordinate of the destination region.

`y` - The minimum Y coordinate of the destination region.

`width` - The width of the destination region.

height - The height of the destination region.  
subsampleBitsH - The desired fixed-point precision of the output X coordinates.  
subsampleBitsV - The desired fixed-point precision of the output Y coordinates.  
destRect - An int array containing at least 2\*width\*height elements, or null. If null, a new array will be constructed.

**Returns:**

A reference to the destRect parameter if it is non-null, or a new int array of length 2\*width\*height otherwise.

---

## warpRect

```
public float[] warpRect(int x,  
                        int y,  
                        int width,  
                        int height,  
                        float[] destRect)
```

Computes the source subpixel positions for a given rectangular destination region. The destination region is specified using normal integral (full pixel) coordinates. The source positions returned by the method are specified in floating point.

As a convenience, an implementation is provided for this method that calls warpSparseRect(). Subclasses may wish to provide their own implementations for better performance.

**Parameters:**

x - The minimum X coordinate of the destination region.  
y - The minimum Y coordinate of the destination region.  
width - The width of the destination region.  
height - The height of the destination region.  
destRect - A float array containing at least 2\*width\*height elements, or null. If null, a new array will be constructed.

**Returns:**

A reference to the destRect parameter if it is non-null, or a new float array of length 2\*width\*height otherwise.

**Throws:**

java.lang.IllegalArgumentException - if destRect is too small.

---

## warpPoint

```
public int[] warpPoint(int x,  
                       int y,  
                       int subsampleBitsH,  
                       int subsampleBitsV,  
                       int[] destRect)
```

Computes the source subpixel position for a given destination pixel. The destination pixel is specified using normal integral (full pixel) coordinates. The source position returned by the method is specified in fixed point, subpixel coordinates using the subsampleBitsH and subsampleBitsV parameters.

As a convenience, an implementation is provided for this method that calls warpSparseRect(). Subclasses may wish to provide their own implementations for better performance.

**Parameters:**

x - The minimum X coordinate of the destination region.  
y - The minimum Y coordinate of the destination region.  
subsampleBitsH - The desired fixed-point precision of the output X coordinates.  
subsampleBitsV - The desired fixed-point precision of the output Y coordinates.  
destRect - An int array containing at least 2 elements, or null. If null, a new array will be constructed.

**Returns:**

A reference to the destRect parameter if it is non-null, or a new int array of length 2 otherwise.

**Throws:**

java.lang.IllegalArgumentException - if destRect is too small.

---

## warpPoint

```
public float[] warpPoint(int x,  
                         int y,  
                         float[] destRect)
```

Computes the source subpixel position for a given destination pixel. The destination pixel is specified using normal integral (full pixel) coordinates. The source position returned by the method is specified in floating point.

As a convenience, an implementation is provided for this method that calls warpSparseRect(). Subclasses may wish to provide their own implementations for better performance.

**Parameters:**

x - The minimum X coordinate of the destination region.  
 y - The minimum Y coordinate of the destination region.  
 destRect - A float array containing at least 2 elements, or null. If null, a new array will be constructed.

**Returns:**

A reference to the destRect parameter if it is non-null, or a new float array of length 2 otherwise.

**Throws:**

java.lang.IllegalArgumentException - if destRect is too small.

**warpSparseRect**

```
public int[] warpSparseRect(int x,
                           int y,
                           int width,
                           int height,
                           int periodX,
                           int periodY,
                           int subsampleBitsH,
                           int subsampleBitsV,
                           int[] destRect)
```

Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period. The destination region is specified using normal integral (full pixel) coordinates. The source positions returned by the method are specified in fixed point, subpixel coordinates using the subsampleBitsH and subsampleBitsV parameters.

As a convenience, an implementation is provided for this method that calls warpSparseRect() with a float destRect parameter. Subclasses may wish to provide their own implementations for better performance.

**Parameters:**

x - the minimum X coordinate of the destination region.  
 y - the minimum Y coordinate of the destination region.  
 width - the width of the destination region.  
 height - the height of the destination region.  
 periodX - the horizontal sampling period.  
 periodY - the horizontal sampling period.  
 subsampleBitsH - The desired fixed-point precision of the output X coordinates.  
 subsampleBitsV - The desired fixed-point precision of the output Y coordinates.  
 destRect - An int array containing at least  $2*((width+periodX-1)/periodX)*((height+periodY-1)/periodY)$  elements, or null. If null, a new array will be constructed.

**Returns:**

A reference to the destRect parameter if it is non-null, or a new int array otherwise.

**Throws:**

java.lang.IllegalArgumentException - if destRect is too small.

**warpSparseRect**

```
public abstract float[] warpSparseRect(int x,
                                       int y,
                                       int width,
                                       int height,
                                       int periodX,
                                       int periodY,
                                       float[] destRect)
```

This method is abstract in this class and must be provided in concrete subclasses.

**Parameters:**

x - The minimum X coordinate of the destination region.  
 y - The minimum Y coordinate of the destination region.  
 width - The width of the destination region.  
 height - The height of the destination region.  
 periodX - The horizontal sampling period.  
 periodY - The vertical sampling period.  
 destRect - A float array containing at least  $2*((width+periodX-1)/periodX)*((height+periodY-1)/periodY)$  elements, or null. If null, a new array will be constructed.

**Returns:**

a reference to the destRect parameter if it is non-null, or a new float array otherwise.

## mapSourceRect

public java.awt.Rectangle **mapSourceRect**(java.awt.Rectangle sourceRect)

Computes a rectangle that is guaranteed to enclose the region of the destination that can potentially be affected by the pixels of a rectangle of a given source. Unlike the corresponding WarpOpImage method, this routine may return null if it is infeasible to compute such a bounding box.

The default implementation in this class returns null.

**Parameters:**

sourceRect - The Rectangle in source coordinates.

**Returns:**

A Rectangle in the destination coordinate system that enclose the region that can potentially be affected by the pixels of a rectangle of a given source, or null.

---

## mapDestRect

public java.awt.Rectangle **mapDestRect**(java.awt.Rectangle destRect)

Computes a rectangle that is guaranteed to enclose the region of the source that is required in order to produce a given rectangular output region. Unlike the corresponding WarpOpImage method, this routine may return null if it is infeasible to compute such a bounding box.

The default implementation in this class returns null.

**Parameters:**

destRect - The Rectangle in destination coordinates.

**Returns:**

A Rectangle in the source coordinate system that is guaranteed to contain all pixels referenced by the output of warpRect( ) on the destination region, or null.

---

## javax.media.jai Class WarpAffine

```
java.lang.Object
|
+-- javax.media.jai.Warp
    |
    +-- javax.media.jai.WarpPolynomial
        |
        +-- javax.media.jai.WarpAffine
```

---

public final class **WarpAffine**  
extends WarpPolynomial

A description of an Affine warp.

The transform is specified as a mapping from destination space to source space. In other words, it is the inverse of the normal specification of an affine image transformation.

The source position (x', y') of a point (x, y) is given by the quadratic bivariate polynomials:

$$x' = p(x, y) = c1 + c2*x + c3*y$$
$$y' = q(x, y) = c4 + c5*x + c6*y$$

WarpAffine is marked final so that it may be more easily inlined.

#### transform

private java.awt.geom.AffineTransform **transform**

---

### Constructor Detail

#### WarpAffine

```
public WarpAffine(float[] xCoeffs,  
                  float[] yCoeffs,  
                  float preScaleX,  
                  float preScaleY,  
                  float postScaleX,  
                  float postScaleY)
```

Constructs a `WarpAffine` with a given transform mapping destination pixels into source space. The transform is given by:

```
x' = xCoeffs[0] + xCoeffs[1]*x + xCoeffs[2]*y;  
y' = yCoeffs[0] + yCoeffs[1]*x + yCoeffs[2]*y;
```

where  $x'$ ,  $y'$  are the source image coordinates and  $x$ ,  $y$  are the destination image coordinates.

**Parameters:**

- `xCoeffs` - The 3 destination to source transform coefficients for the X coordinate.
- `yCoeffs` - The 3 destination to source transform coefficients for the Y coordinate.
- `preScaleX` - The scale factor to apply to input (dest) X positions.
- `preScaleY` - The scale factor to apply to input (dest) Y positions.
- `postScaleX` - The scale factor to apply to the evaluated x transform
- `postScaleY` - The scale factor to apply to the evaluated y transform

**Throws:**

`java.lang.IllegalArgumentException` - if array `xCoeffs` or `yCoeffs` does not have length of 3.

---

## WarpAffine

```
public WarpAffine(float[] xCoeffs,  
                  float[] yCoeffs)
```

Constructs a `WarpAffine` with pre- and post-scale factors of 1.

**Parameters:**

- `xCoeffs` - The 3 destination to source transform coefficients for the X coordinate.
- `yCoeffs` - The 3 destination to source transform coefficients for the Y coordinate.

---

## WarpAffine

```
public WarpAffine(java.awt.geom.AffineTransform transform,  
                  float preScaleX,  
                  float preScaleY,  
                  float postScaleX,  
                  float postScaleY)
```

Constructs a `WarpAffine` with a given transform mapping destination pixels into source space. Note that this is the inverse of the customary specification of affine mapping of an image.

**Parameters:**

- `transform` - The destination to source transform.
- `preScaleX` - The scale factor to apply to source X positions.
- `preScaleY` - The scale factor to apply to source Y positions.
- `postScaleX` - The scale factor to apply to destination X positions.
- `postScaleY` - The scale factor to apply to destination Y positions.

---

## WarpAffine

```
public WarpAffine(java.awt.geom.AffineTransform transform)
```

Constructs a `WarpAffine` with pre- and post-scale factors of 1.

**Parameters:**

- `transform` - An `AffineTransform` mapping dest to source coordinates.

---

## Method Detail

### xCoeffsHelper

```
private static final float[] xCoeffsHelper(java.awt.geom.AffineTransform transform)
```

**Parameters:**

- `transform` -

**Returns:**

- An array of floats.

---

### yCoeffsHelper

```
private static final float[] yCoeffsHelper(java.awt.geom.AffineTransform transform)
```

---

## getTransform

```
public java.awt.geom.AffineTransform getTransform()
```

Returns a clone of the AffineTransform associated with this WarpAffine object.

**Returns:**

An AffineTransform.

---

## warpSparseRect

```
public float[] warpSparseRect(int x,  
                               int y,  
                               int width,  
                               int height,  
                               int periodX,  
                               int periodY,  
                               float[] destRect)
```

Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period. The destination region is specified using normal integral (full pixel) coordinates. The source positions returned by the method are specified in floating point.

**Parameters:**

x - The minimum X coordinate of the destination region.

y - The minimum Y coordinate of the destination region.

width - The width of the destination region.

height - The height of the destination region.

periodX - The horizontal sampling period.

periodY - The vertical sampling period.

destRect - A float array containing at least  $2 * ((width + periodX - 1) / periodX) * ((height + periodY - 1) / periodY)$  elements, or null. If null, a new array will be constructed.

**Returns:**

A reference to the destRect parameter if it is non-null, or a new float array otherwise.

**Overrides:**

warpSparseRect in class Warp

---

## mapDestRect

```
public java.awt.Rectangle mapDestRect(java.awt.Rectangle destRect)
```

Computes a Rectangle that is guaranteed to enclose the region of the source that is required in order to produce a given rectangular output region.

**Parameters:**

destRect - The Rectangle in destination coordinates.

**Returns:**

A Rectangle in the source coordinate system that is guaranteed to contain all pixels referenced by the output of warpRect() on the destination region, or null.

**Throws:**

NullPointerException - if destRect is null.

**Overrides:**

mapDestRect in class WarpPolynomial

---

## mapDestPoint

```
private float[] mapDestPoint(int x,  
                               int y)
```

---

## javax.media.jai Class WarpCubic

```
java.lang.Object
|
+-- javax.media.jai.Warp
    |
    +-- javax.media.jai.WarpPolynomial
        |
        +-- javax.media.jai.WarpCubic
```

---

public final class **WarpCubic**  
extends WarpPolynomial

A cubic-based description of an image warp.

The source position (x', y') of a point (x, y) is given by the cubic polynomial:

$$\begin{aligned} x' &= p(x, y) = c1 + c2*x + c3*y + c4*x^2 + c5*x*y + c6*y^2 + \\ &\quad c7*x^3 + c8*x^2*y + c9*x*y^2 + c10*y^3 \\ y' &= q(x, y) = c11 + c12*x + c13*y + c14*x^2 + c15*x*y + c16*y^2 + \\ &\quad c17*x^3 + c18*x^2*y + c19*x*y^2 + c20*y^3 \end{aligned}$$

WarpCubic is marked final so that it may be more easily inlined.

<b>Constructor Detail</b>
---------------------------

**WarpCubic**

```
public WarpCubic(float[] xCoeffs,  
                 float[] yCoeffs,  
                 float preScaleX,  
                 float preScaleY,  
                 float postScaleX,  
                 float postScaleY)
```

Constructs a WarpCubic with a given transform mapping destination pixels into source space. Note that this is the inverse of the customary specification of the mapping of an image. The coeffs arrays must each contain 10 floats corresponding to the coefficients c1, c2, etc. as shown in the class comment.

**Parameters:**

xCoeffs - The 10 destination to source transform coefficients for the X coordinate.  
 yCoeffs - The 10 destination to source transform coefficients for the Y coordinate.  
 preScaleX - The scale factor to apply to input (dest) X positions.  
 preScaleY - The scale factor to apply to input (dest) Y positions.  
 postScaleX - The scale factor to apply to the result of the X polynomial evaluation  
 postScaleY - The scale factor to apply to the result of the Y polynomial evaluation

**Throws:**

java.lang.IllegalArgumentException - if the length of the xCoeffs and yCoeffs arrays are not both 10.

## WarpCubic

```
public WarpCubic(float[] xCoeffs,
                 float[] yCoeffs)
```

Constructs a WarpCubic with pre- and post-scale factors of 1.

**Parameters:**

xCoeffs - The 10 destination to source transform coefficients for the X coordinate.  
 yCoeffs - The 10 destination to source transform coefficients for the Y coordinate.

**Throws:**

java.lang.IllegalArgumentException - if the length of the xCoeffs and yCoeffs arrays are not both 10.

## Method Detail

### warpSparseRect

```
public float[] warpSparseRect(int x,
                              int y,
                              int width,
                              int height,
                              int periodX,
                              int periodY,
                              float[] destRect)
```

Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period. The destination region is specified using normal integral (full pixel) coordinates. The source positions returned by the method are specified in floating point.

**Parameters:**

x - The minimum X coordinate of the destination region.  
 y - The minimum Y coordinate of the destination region.  
 width - The width of the destination region.  
 height - The height of the destination region.  
 periodX - The horizontal sampling period.  
 periodY - The vertical sampling period.  
 destRect - A float array containing at least  $2 * ((width + periodX - 1) / periodX) * ((height + periodY - 1) / periodY)$  elements, or null. If null, a new array will be constructed.

**Returns:**

A reference to the destRect parameter if it is non-null, or a new float array otherwise.

**Throws:**

ArrayBoundsException - if destRect is too small

**Overrides:**

warpSparseRect in class Warp

---

## javax.media.jai

### Class WarpGeneralPolynomial

```
java.lang.Object
|
+-- javax.media.jai.Warp
    |
    +-- javax.media.jai.WarpPolynomial
        |
        +-- javax.media.jai.WarpGeneralPolynomial
```

---

public final class **WarpGeneralPolynomial**

extends WarpPolynomial

A general polynomial-based description of an image warp.

The mapping is defined by two bivariate polynomial functions  $X(x, y)$  and  $Y(x, y)$  that define the source  $X$  and  $Y$  positions that map to a given destination  $(x, y)$  pixel coordinate.

The functions  $X(x, y)$  and  $Y(x, y)$  have the form:

$$\text{SUM}\{i = 0 \text{ to } n\} \{ \text{SUM}\{j = 0 \text{ to } i\} \{ a_{ij} * x^{(i-j)} * y^j \} \}$$

**See Also:**

WarpPolynomial

---

## Constructor Detail

### WarpGeneralPolynomial

```
public WarpGeneralPolynomial(float[] xCoeffs,
                             float[] yCoeffs,
                             float preScaleX,
                             float preScaleY,
                             float postScaleX,
                             float postScaleY)
```

Constructs a WarpGeneralPolynomial with a given transform mapping destination pixels into source space. Note that this is the inverse of the customary specification of the mapping of an image.

The `xCoeffs` and `yCoeffs` parameters must contain the same number of coefficients of the form  $(n + 1)(n + 2)/2$  for some  $n$ , where  $n$  is the non-negative degree power of the polynomial. The coefficients, in order, are associated with the terms:

1,  $x$ ,  $y$ ,  $x^2$ ,  $x*y$ ,  $y^2$ , ...,  $x^n$ ,  $x^{(n-1)}*y$ , ...,  $x*y^{(n-1)}$ ,  $y^n$

and coefficients of value 0 cannot be omitted.

The destination pixel coordinates (the arguments to the `X()` and `Y()` functions) are given in normal integral pixel coordinates, while the output of the functions is given in fixed-point, subpixel coordinates with a number of fractional bits specified by the `subsampleBitsH` and `subsampleBitsV` parameters.

**Parameters:**

`xCoeffs` - The destination to source transform coefficients for the  $X$  coordinate.

`yCoeffs` - The destination to source transform coefficients for the  $Y$  coordinate.

`preScaleX` - The scale factor to apply to input (dst)  $X$  positions.

`preScaleY` - The scale factor to apply to input (dst)  $Y$  positions.

`postScaleX` - The scale factor to apply to output (src)  $X$  positions.

`postScaleY` - The scale factor to apply to output (src)  $Y$  positions.

**Throws:**

`java.lang.IllegalArgumentException` - if arrays `xCoeffs` and `yCoeffs` do not have the correct number of entries.

---

### WarpGeneralPolynomial

```
public WarpGeneralPolynomial(float[] xCoeffs,
                             float[] yCoeffs)
```

Constructs a WarpGeneralPolynomial with pre- and post-scale factors of 1.

**Parameters:**

`xCoeffs` - The destination to source transform coefficients for the  $X$  coordinate.

`yCoeffs` - The destination to source transform coefficients for the  $Y$  coordinate.

**Throws:**

`java.lang.IllegalArgumentException` - if arrays `xCoeffs` and `yCoeffs` do not have the correct number of entries.

## Method Detail

### warpSparseRect

```
public float[] warpSparseRect(int x,  
                             int y,  
                             int width,  
                             int height,  
                             int periodX,  
                             int periodY,  
                             float[] destRect)
```

Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period.

**Parameters:**

x - The minimum X coordinate of the destination region.  
y - The minimum Y coordinate of the destination region.  
width - The width of the destination region.  
height - The height of the destination region.  
periodX - The horizontal sampling period.  
periodY - The vertical sampling period.  
destRect - An int array containing at least  $2*((width+periodX-1)/periodX)*((height+periodY-1)/periodY)$  elements, or null. If null, a new array will be constructed.

**Returns:**

a reference to the destRect parameter if it is non-null, or a new int array of length  $2*width*height$  otherwise.

**Throws:**

ArrayBoundsException - if destRect array is too small

**Overrides:**

warpSparseRect in class Warp

---

## javax.media.jai Class WarpGrid

```
java.lang.Object
|
+-- javax.media.jai.Warp
|
+-- javax.media.jai.WarpGrid
```

---

public final class **WarpGrid**  
extends Warp

A regular grid-based description of an image warp.

The mapping from destination pixels to source positions is described by bilinear interpolation between a rectilinear grid of points with known mappings.

Given a destination pixel coordinate (x, y) that lies within a cell having corners at (x0, y0), (x1, y0), (x0, y1) and (x1, y1), with source coordinates defined at each respective corner equal to (sx0, sy0), (sx1, sy1), (sx2, sy2) and (sx3, sy3), the source position (sx, sy) that maps onto (x, y) is given by the formulas:

```
xfrac = (x - x0)/(x1 - x0)
yfrac = (y - y0)/(y1 - y0)
```

```
s = sx0 + (sx1 - sx0)*xfrac
t = sy0 + (sy1 - sy0)*xfrac
```

```
u = sx2 + (sx3 - sx2)*xfrac
v = sy2 + (sy3 - sy2)*xfrac
```

```
sx = s + (u - s)*yfrac
sy = t + (v - t)*yfrac
```

In other words, the source x and y values are interpolated horizontally along the top and bottom edges of the grid cell, and the results are interpolated vertically:

WarpGrid is marked final so that it may be more easily inlined.

### **WarpGrid**

```
public WarpGrid(int xStart,  
                int xStep,  
                int xNumCells,  
                int yStart,  
                int yStep,  
                int yNumCells,  
                float[] warpPositions)
```

Constructs a WarpGrid with a given grid-based transform mapping destination pixels into source space. Note that this is the inverse of the customary specification of the mapping of an image.

The grid is defined by a set of equal-sized cells. The grid starts at (xStart, yStart). Each cell has width equal to xStep and height equal to yStep, and there are xNumCells cells horizontally and yNumCells cells vertically.

The degree of warping within each cell is defined by the values in the table parameter. This parameter must contain  $2 \times (\text{xNumCells} + 1) \times (\text{yNumCells} + 1)$  values, which alternately contain the source X and Y coordinates to which each destination grid intersection point maps. The cells are enumerated in row-major order, that is, all the grid points along a row are enumerated first, then the grid points for the next row are enumerated, and so on.

As an example, suppose xNumCells is equal to 2 and yNumCells is equal 1. Then the order of the data in table would be:

```
x00, y00, x10, y10, x20, y20, x01, y01, x11, y11, x21, y21
```

for a total of  $2 \times (2 + 1) \times (1 + 1) = 12$  elements.

#### **Parameters:**

xStart - the minimum X coordinate of the grid.

xStep - the horizontal spacing between grid cells.

xNumCells - the number of grid cell columns.

yStart - the minimum Y coordinate of the grid.

yStep - the vertical spacing between grid cells.

yNumCells - the number of grid cell rows.

warpPositions - a float array of length  $2 \times (\text{xNumCells} + 1) \times (\text{yNumCells} + 1)$  containing the warp positions at the grid points, in row-major order.

**Throws:**

java.lang.IllegalArgumentException - if the length of warpPositions is incorrect

---

## WarpGrid

```
public WarpGrid(Warp master,
                int xStart,
                int xStep,
                int xNumCells,
                int yStart,
                int yStep,
                int yNumCells)
```

Constructs a WarpGrid object by sampling the displacements given by another Warp object of any kind.

The grid is defined by a set of equal-sized cells. The grid starts at (xStart, yStart). Each cell has width equal to xStep and height equal to yStep, and there are xNumCells cells horizontally and yNumCells cells vertically.

**Parameters:**

master - the Warp object used to initialize the grid displacements.  
xStart - the minimum X coordinate of the grid.  
xStep - the horizontal spacing between grid cells.  
xNumCells - the number of grid cell columns.  
yStart - the minimum Y coordinate of the grid.  
yStep - the vertical spacing between grid cells.  
yNumCells - the number of grid cell rows.

## Method Detail

### initialize

```
private void initialize(int xStart,
                       int xStep,
                       int xNumCells,
                       int yStart,
                       int yStep,
                       int yNumCells,
                       float[] warpPositions)
```

**Parameters:**

xStart -  
xStep -  
xNumCells -  
yStart -  
yStep -  
yNumCells -  
warpPositions -

---

### getXStart

```
public int getXStart()
```

Returns the minimum X coordinate of the grid.

---

### getYStart

```
public int getYStart()
```

Returns the minimum Y coordinate of the grid.

---

### getXStep

```
public int getXStep()
```

Returns the horizontal spacing between grid cells.

---

## getYStep

```
public int getYStep()
```

Returns the horizontal spacing between grid cells.

---

## getXNumCells

```
public int getXNumCells()
```

Returns the number of grid cell columns.

---

## getYNumCells

```
public int getYNumCells()
```

Returns the number of grid cell columns.

---

## getXWarpPos

```
public float[] getXWarpPos()
```

Returns the horizontal warp positions at the grid points.

---

## getYWarpPos

```
public float[] getYWarpPos()
```

Returns the horizontal warp positions at the grid points.

---

## noWarpSparseRect

```
private float[] noWarpSparseRect(int x1,
                                int x2,
                                int y1,
                                int y2,
                                int periodX,
                                int periodY,
                                int offset,
                                int stride,
                                float[] destRect)
```

Copies source to destination, no warpping.

### Parameters:

x1 -  
x2 -  
y1 -  
y2 -  
periodX -  
periodY -  
offset -  
stride -  
destRect -

### Returns:

An array of floats.

### Throws:

NullPointerException - if destRect is null  
ArrayBoundsException - if destRect is too small

---

## warpSparseRect

```
public float[] warpSparseRect(int x,
                              int y,
                              int width,
                              int height,
                              int periodX,
                              int periodY,
                              float[] destRect)
```

Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period.

**Parameters:**

x - The minimum X coordinate of the destination region.  
y - The minimum Y coordinate of the destination region.  
width - The width of the destination region.  
height - The height of the destination region.  
periodX - The horizontal sampling period.  
periodY - The vertical sampling period.  
destRect - An int array containing at least  $2*((width+periodX-1)/periodX)*((height+periodY-1)/periodY)$  elements, or null. If null, a new array will be constructed.

**Returns:**

a reference to the destRect parameter if it is non-null, or a new int array of length  $2*width*height$  otherwise.

**Throws:**

NullPointerException - if destRect is null  
ArrayBoundsException - if destRect is too small

**Overrides:**

warpSparseRect in class Warp

---

## mapDestRect

```
public java.awt.Rectangle mapDestRect(java.awt.Rectangle destRect)
```

Computes a Rectangle that is guaranteed to enclose the region of the source that is required in order to produce a given rectangular output region.

**Parameters:**

destRect - The Rectangle in destination coordinates.

**Returns:**

A Rectangle in the source coordinate system that is guaranteed to contain all pixels referenced by the output of warpRect() on the destination region, or null.

**Throws:**

NullPointerException - if destRect is null.

**Overrides:**

mapDestRect in class Warp

---

## javax.media.jai Class WarpOpImage

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
|   |
|   +-- javax.media.jai.OpImage
|       |
|       +-- javax.media.jai.WarpOpImage
```

### Direct Known Subclasses:

ScaleOpImage

---

public abstract class **WarpOpImage**

extends OpImage

A general implementation of image warping, and a superclass for other geometric image operations.

The image warp is specified by a Warp object and an Interpolation object.

Subclasses of WarpOpImage may choose whether they wish to implement the cobbled or non-cobbled variant of computeRect by means of the cobbleSources constructor parameter. The class comments for OpImage provide more information about how to override computeRect.

### See Also:

OpImage, ScaleOpImage, Warp, Interpolation

---

## Field Detail

### warp

protected Warp **warp**

The Warp object describing the backwards pixel map.

---

### interp

protected Interpolation **interp**

The Interpolation object describing the subpixel interpolation method.

---

### writableBounds

protected java.awt.Rectangle **writableBounds**

The writable boundary of this image. By default, this is determined based on the boundary of the source image, the type of the border extender, and the interpolation method. Subclasses should set this variable based on individual cases.

---

## Constructor Detail

### WarpOpImage

```
public WarpOpImage(java.awt.image.RenderedImage source,
                  BorderExtender extender,
                  TileCache cache,
                  ImageLayout layout,
                  Warp warp,
                  Interpolation interp,
                  boolean cobbleSources)
```

Constructs a WarpOpImage. The output minX, minY, width, and height are derived from the source image unless overridden by the layout parameter. The SampleModel and ColorModel of the output are set in the standard way by the OpImage constructor.

Additional control over the image bounds, tile grid layout, SampleModel, and ColorModel may be obtained by specifying an ImageLayout parameter. This parameter will be passed to the superclass constructor unchanged.

#### Parameters:

source - A RenderedImage.

extender - A BorderExtender, or null.

cache - A TileCache object to store tiles from this OpImage, or null. If null, a default cache will be used.

layout - An ImageLayout optionally containing the tile grid layout, SampleModel, and ColorModel.

warp - The Warp object describing the warp.

`interp` - The `Interpolation` object describing the interpolation method.

`cobbleSources` - A boolean indicating whether `computeRect()` expects contiguous sources. To use the default implementation of warping contained in this class, set `cobbleSources` to `false`.

**Throws:**

`java.lang.IllegalArgumentException` - if combining the source bounds with the layout parameter results in negative output width or height.

## Method Detail

### **getLeftPadding**

```
public int getLeftPadding()
```

Returns the number of samples required to the left of the center.

**Returns:**

The left padding factor.

### **getRightPadding**

```
public int getRightPadding()
```

Returns the number of samples required to the right of the center.

**Returns:**

The right padding factor.

### **getTopPadding**

```
public int getTopPadding()
```

Returns the number of samples required above the center.

**Returns:**

The top padding factor.

### **getBottomPadding**

```
public int getBottomPadding()
```

Returns the number of samples required below the center.

**Returns:**

The bottom padding factor.

### **mapSourceRect**

```
public java.awt.Rectangle mapSourceRect(java.awt.Rectangle sourceRect,  
                                           int sourceIndex)
```

Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**Parameters:**

`sourceRect` - The `Rectangle` in source coordinates.

`sourceIndex` - The index of the source image.

**Returns:**

a `Rectangle` indicating the potentially affected destination region, or `null` if the region is unknown.

**Throws:**

`java.lang.IllegalArgumentException` - if `sourceIndex` is negative or greater than the index of the last source.

`NullPointerException` - if `sourceRect` is `null`.

**Overrides:**

`mapSourceRect` in class `OpImage`

### **mapDestRect**

```
public java.awt.Rectangle mapDestRect(java.awt.Rectangle destRect,  
                                         int sourceIndex)
```

Returns a conservative estimate of the region of a specified source that is required in order to compute the pixels of a given destination rectangle.

**Parameters:**

`destRect` - The `Rectangle` in destination coordinates.

`sourceIndex` - The index of the source image.

**Returns:**

a `Rectangle` indicating the required source region.

**Throws:**

`java.lang.IllegalArgumentException` - if `sourceIndex` is negative or greater than the index of the last source.

`NullPointerException` - if `destRect` is null.

**Overrides:**

`mapDestRect` in class `OpImage`

---

## **computeTile**

```
public java.awt.image.Raster computeTile(int tileX,  
                                           int tileY)
```

Computes a tile. A new `WritableRaster` is created to represent the requested tile. Its width and height equals to this image's tile width and tile height respectively. If the requested tile lies outside of the image's boundary, the created raster is returned with all of its pixels set to 0.

Whether or not this method performs source cobbling is determined by the `cobbleSources` variable set at construction time. If `cobbleSources` is true, cobbling is performed on the source for areas that intersect multiple tiles, and `computeRect(Raster[], WritableRaster, Rectangle)` is called to perform the actual computation. Otherwise, `computeRect(PlanarImage[], WritableRaster, Rectangle)` is called to perform the actual computation.

**Parameters:**

`tileX` - The X index of the tile.

`tileY` - The Y index of the tile.

**Returns:**

The tile as a `Raster`.

**Overrides:**

`computeTile` in class `OpImage`

---

## javafx.media.jai Class WarpPerspective

```
java.lang.Object
|
+--javafx.media.jai.Warp
|
+--javafx.media.jai.WarpPerspective
```

---

public final class **WarpPerspective**  
extends Warp

A description of a perspective (projective) warp.

The transform is specified as a mapping from destination space to source space. In other words, it is the inverse of the normal specification of a perspective image transformation.

WarpPerspective is marked final so that it may be more easily inlined.

---

### Field Detail

#### transform

private PerspectiveTransform **transform**

---

### Constructor Detail

#### WarpPerspective

public **WarpPerspective**(PerspectiveTransform transform)

Constructs a WarpPerspective with a given transform mapping destination pixels into source space. Note that this is the inverse of the customary specification of perspective mapping of an image.

**Parameters:**

transform - The destination to source transform.

**Throws:**

java.lang.IllegalArgumentException - if transform is null

---

### Method Detail

#### getTransform

public PerspectiveTransform **getTransform**()

Returns a clone of the PerspectiveTransform associated with this WarpPerspective object.

**Returns:**

An instance of PerspectiveTransform.

---

#### warpSparseRect

```
public float[] warpSparseRect(int x,  
                               int y,  
                               int width,  
                               int height,  
                               int periodX,  
                               int periodY,  
                               float[] destRect)
```

Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period. The destination region is specified using normal integral (full pixel) coordinates. The source positions returned by the method are specified in floating point.

**Parameters:**

x - The minimum X coordinate of the destination region.

y - The minimum Y coordinate of the destination region.

width - The width of the destination region.

height - The height of the destination region.

periodX - The horizontal sampling period.

periodY - The horizontal sampling period.

destRect - A float array containing at least  $2 * ((width + periodX - 1) / periodX) * ((height + periodY - 1) / periodY)$  elements, or null. If null, a new array will be constructed.

**Returns:**

A reference to the `destRect` parameter if it is non-null, or a new `float` array otherwise.

**Overrides:**

`warpSparseRect` in class `Warp`

---

**mapDestRect**

```
public java.awt.Rectangle mapDestRect(java.awt.Rectangle destRect)
```

Computes a `Rectangle` that is guaranteed to enclose the region of the source that is required in order to produce a given rectangular output region.

**Parameters:**

`destRect` - the `Rectangle` in destination coordinates.

**Returns:**

A `Rectangle` in the source coordinate system that is guaranteed to contain all pixels referenced by the output of `warpRect()` on the destination region.

**Overrides:**

`mapDestRect` in class `Warp`

---

## javax.media.jai Class WarpPolynomial

```
java.lang.Object
|
+-- javax.media.jai.Warp
|
+-- javax.media.jai.WarpPolynomial
```

### Direct Known Subclasses:

WarpAffine, WarpCubic, WarpGeneralPolynomial, WarpQuadratic

---

public abstract class **WarpPolynomial**  
extends Warp

A polynomial-based description of an image warp.

The mapping is defined by two bivariate polynomial functions  $X(x, y)$  and  $Y(x, y)$  that map destination  $(x, y)$  coordinates to source  $X$  and  $Y$  positions respectively

The functions  $X(x, y)$  and  $Y(x, y)$  have the form:

$$\text{SUM}\{i = 0 \text{ to } n\} \{ \text{SUM}\{j = 0 \text{ to } i\} \{ a_{ij} * x^{(i-j)} * y^j \} \}$$

WarpAffine, WarpQuadratic, and WarpCubic are special cases of WarpPolynomial for  $n$  equal to 1, 2, and 3 respectively.

WarpGeneralPolynomial provides a concrete implementation for polynomials of higher degree.

### See Also:

WarpAffine, WarpQuadratic, WarpCubic, WarpGeneralPolynomial

---

## Field Detail

### xCoeffs

protected float[] **xCoeffs**

An array of coefficients that maps a destination point to the source's  $X$  coordinate.

---

### yCoeffs

protected float[] **yCoeffs**

An array of coefficients that maps a destination point to the source's  $Y$  coordinate.

---

### preScaleX

protected float **preScaleX**

A scaling factor applied to input (dest)  $x$  coordinates to which may improve computational accuracy.

---

### preScaleY

protected float **preScaleY**

A scaling factor applied to input (dest)  $y$  coordinates to which may improve computational accuracy.

---

### postScaleX

protected float **postScaleX**

A scaling factor applied to the result of the  $X$  polynomial evaluation which compensates for the input scaling, so that the correctly scaled result is achieved.

---

### postScaleY

protected float **postScaleY**

A scaling factor applied to the result of the  $Y$  polynomial evaluation which compensates for the input scaling, so that the correctly scaled result is achieved.

---

---

## degree

protected int **degree**

The degree of the polynomial, determined by the number of coefficients supplied via the X and Y coefficients arrays.

### Constructor Detail

#### WarpPolynomial

```
public WarpPolynomial(float[] xCoeffs,
                      float[] yCoeffs,
                      float preScaleX,
                      float preScaleY,
                      float postScaleX,
                      float postScaleY)
```

Constructs a WarpPolynomial with a given transform mapping destination pixels into source space. Note that this is the inverse of the customary specification of the mapping of an image.

The `xCoeffs` and `yCoeffs` parameters must contain the same number of coefficients of the form  $(n + 1)(n + 2)/2$  for some  $n$ , where  $n$  is the non-negative degree power of the polynomial. The coefficients, in order, are associated with the terms:

$1, x, y, x^2, x*y, y^2, \dots, x^n, x^{(n-1)}*y, \dots, x*y^{(n-1)}, y^n$   
and coefficients of value 0 cannot be omitted.

The source  $(x, y)$  coordinate is pre-scaled by the factors `preScaleX` and `preScaleY` prior to the evaluation of the polynomial. The result of the polynomial evaluations are scaled by `postScaleX` and `postScaleY` to produce the destination pixel coordinates. This process allows for better precision of the results.

**Parameters:**

`xCoeffs` - The destination to source transform coefficients for the X coordinate.  
`yCoeffs` - The destination to source transform coefficients for the Y coordinate.  
`preScaleX` - The scale factor to apply to input (dest) X positions.  
`preScaleY` - The scale factor to apply to input (dest) Y positions.  
`postScaleX` - The scale factor to apply to the X polynomial output.  
`postScaleY` - The scale factor to apply to the Y polynomial output.

**Throws:**

`java.lang.IllegalArgumentException` - if `xCoeff` or `yCoeff` have an illegal number of entries.

---

#### WarpPolynomial

```
public WarpPolynomial(float[] xCoeffs,
                      float[] yCoeffs)
```

Constructs a WarpPolynomial with pre- and post-scale factors of 1.

**Parameters:**

`xCoeffs` - The destination to source transform coefficients for the X coordinate.  
`yCoeffs` - The destination to source transform coefficients for the Y coordinate.

### Method Detail

#### getXCoeffs

```
public float[] getXCoeffs()
```

Returns the raw coefficients array for the X coordinate.

**Returns:**

A cloned array of `floats` giving the polynomial coefficients for the X coordinate.

---

#### getYCoeffs

```
public float[] getYCoeffs()
```

Returns the raw coefficients array for the Y coordinate.

**Returns:**

A cloned array of `floats` giving the polynomial coefficients for the Y coordinate.

---

## getCoeffs

```
public float[][] getCoeffs()
```

Returns the raw coefficients array for both the X and Y coordinates.

**Returns:**

A cloned two-dimensional array of floats giving the polynomial coefficients for the X and Y coordinate.

---

## getPreScaleX

```
public float getPreScaleX()
```

Returns the scaling factor applied to input (dest) X coordinates.

---

## getPreScaleY

```
public float getPreScaleY()
```

Returns the scaling factor applied to input (dest) Y coordinates.

---

## getPostScaleX

```
public float getPostScaleX()
```

Returns the scaling factor applied to the result of the X polynomial.

---

## getPostScaleY

```
public float getPostScaleY()
```

Returns the scaling factor applied to the result of the Y polynomial.

---

## getDegree

```
public int getDegree()
```

Returns the degree of the warp polynomials.

**Returns:**

The degree as an int.

---

## createWarp

```
public static WarpPolynomial createWarp(float[] sourceCoords,
                                         int sourceOffset,
                                         float[] destCoords,
                                         int destOffset,
                                         int numCoords,
                                         float preScaleX,
                                         float preScaleY,
                                         float postScaleX,
                                         float postScaleY,
                                         int degree)
```

Returns an instance of WarpPolynomial or its subclasses that approximately maps the given scaled destination image coordinates into the given scaled source image coordinates. The mapping is given by:

```
x' = postScaleX*(xpoly(x*preScaleX, y*preScaleY));
y' = postScaleY*(ypoly(x*preScaleX, y*preScaleY));
```

Typically, it is useful to set preScaleX to  $1.0F/\text{destImage.getWidth}()$  and postScaleX to  $\text{srcImage.getWidth}()$  so that the input and output of the polynomials lie between 0 and 1.

The degree of the polynomial is supplied as an argument.

**Parameters:**

sourceCoords - An array of floats containing the source coordinates with X and Y alternating.

sourceOffset - the initial entry of sourceCoords to be used.

destCoords - An array of floats containing the destination coordinates with X and Y alternating.

destOffset - The initial entry of destCoords to be used.

numCoords - The number of coordinates from sourceCoords and destCoords to be used.

preScaleX - The scale factor to apply to input (dest) X positions.

preScaleY - The scale factor to apply to input (dest) Y positions.

postScaleX - The scale factor to apply to X polynomial output.

postScaleY - The scale factor to apply to the Y polynomial output.

degree - The desired degree of the warp polynomials.

**Returns:**

An instance of WarpPolynomial.

**Throws:**

java.lang.IllegalArgumentException - if arrays sourceCoords or destCoords are too small

---

**mapDestRect**

```
public java.awt.Rectangle mapDestRect(java.awt.Rectangle destRect)
```

Computes a Rectangle that is guaranteed to enclose the region of the source that is required in order to produce a given rectangular output region.

**Parameters:**

destRect - The Rectangle in destination coordinates.

**Returns:**

A Rectangle in the source coordinate system that is guaranteed to contain all pixels referenced by the output of warpRect( ) on the destination region, or null.

**Throws:**

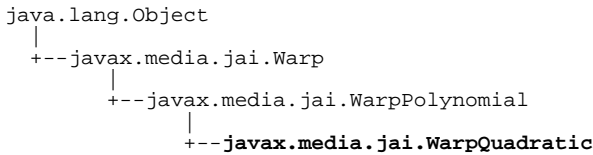

NullPointerException - if destRect is null.

**Overrides:**

mapDestRect in class Warp

---

**javax.media.jai**  
**Class WarpQuadratic**

public final class **WarpQuadratic**  
extends WarpPolynomial

A quadratic-based description of an image warp.

The source position (x', y') of a point (x, y) is given by the quadratic bivariate polynomials:

$x' = p(x, y) = c1 + c2*x + c3*y + c4*x^2 + c5*x*y + c6*y^2$   
 $y' = q(x, y) = c7 + c8*x + c9*y + c10*x^2 + c11*x*y + c12*y^2$

WarpQuadratic is marked final so that it may be more easily inlined.

**See Also:**  
WarpPolynomial

## Constructor Detail

### WarpQuadratic

```
public WarpQuadratic(float[] xCoeffs,
                     float[] yCoeffs,
                     float preScaleX,
                     float preScaleY,
                     float postScaleX,
                     float postScaleY)
```

Constructs a `WarpQuadratic` with a given transform mapping destination pixels into source space. Note that this is the inverse of the customary specification of the mapping of an image. The coeffs arrays must each contain 6 floats corresponding to the coefficients c1, c2, etc. as shown in the class comment.

**Parameters:**

`xCoeffs` - The six destination to source transform coefficients for the X coordinate.  
`yCoeffs` - The six destination to source transform coefficients for the Y coordinate.  
`preScaleX` - The scale factor to apply to input (dest) X positions.  
`preScaleY` - The scale factor to apply to input (dest) Y positions.  
`postScaleX` - The scale factor to apply to the result of the X polynomial evaluation  
`postScaleY` - The scale factor to apply to the result of the Y polynomial evaluation

**Throws:**

`java.lang.IllegalArgumentException` - if the `xCoeff` and `yCoeff` arrays do not each have size entries.

---

### WarpQuadratic

```
public WarpQuadratic(float[] xCoeffs,
                     float[] yCoeffs)
```

Constructs a `WarpQuadratic` with pre- and post-scale factors of 1.

**Parameters:**

`xCoeffs` - The 6 destination to source transform coefficients for the X coordinate.  
`yCoeffs` - The 6 destination to source transform coefficients for the Y coordinate.

**Throws:**

`java.lang.IllegalArgumentException` - if the `xCoeff` and `yCoeff` arrays do not each have size entries.

---

## Method Detail

### warpSparseRect

```
public float[] warpSparseRect(int x,
                             int y,
                             int width,
                             int height,
                             int periodX,
                             int periodY,
                             float[] destRect)
```

Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period. The destination region is specified using normal integral (full pixel) coordinates. The source positions returned by the method are specified in floating point.

**Parameters:**

`x` - The minimum X coordinate of the destination region.  
`y` - The minimum Y coordinate of the destination region.  
`width` - The width of the destination region.  
`height` - The height of the destination region.  
`periodX` - The horizontal sampling period.  
`periodY` - The vertical sampling period.  
`destRect` - A float array containing at least  $2 * ((width + periodX - 1) / periodX) * ((height + periodY - 1) / periodY)$  elements, or null. If null, a new array will be constructed.

**Returns:**

A reference to the `destRect` parameter if it is non-null, or a new float array otherwise.

**Throws:**

`ArrayBoundsException` - if `destRect` is too small

**Overrides:**

`warpSparseRect` in class `Warp`

---

## javax.media.jai Class WritableRasterJAI

```
java.lang.Object
|
+--java.awt.image.Raster
|   |
|   +--java.awt.image.WritableRaster
|       |
|       +--javax.media.jai.WritableRasterJAI
```

---

```
class WritableRasterJAI
extends java.awt.image.WritableRaster
```

---

### Constructor Detail

#### WritableRasterJAI

```
protected WritableRasterJAI(java.awt.image.SampleModel sampleModel,
                             java.awt.image.DataBuffer dataBuffer,
                             java.awt.Rectangle aRegion,
                             java.awt.Point sampleModelTranslate,
                             java.awt.image.WritableRaster parent)
```

---

## javax.media.jai Class WritableRenderedImageAdapter

```
java.lang.Object
|
+-- javax.media.jai.PlanarImage
    |
    +-- javax.media.jai.RenderedImageAdapter
        |
        +-- javax.media.jai.WritableRenderedImageAdapter
```

---

public final class **WritableRenderedImageAdapter**  
extends `RenderedImageAdapter`  
implements `java.awt.image.WritableRenderedImage`

A `PlanarImage` wrapper for a `WritableRenderedImage`. The tile layout, sample model, and so forth are preserved. Calls to `getTile()` and so forth are forwarded.

From JAI's point of view, this image is a `PlanarImage` of unknown type, with no sources, and additionally an implementer of the `WritableRenderedImage` interface. The image's pixel data appear to be variable.

The class and all its methods are marked `final` in order to allow dynamic inlining to take place. This should eliminate any performance penalty associated with the use of an adapter class.

### See Also:

`PlanarImage`, `RenderedImage`, `RenderedImageAdapter`, `WritableRenderedImage`

---

## Field Detail

### theImage

private `java.awt.image.WritableRenderedImage` **theImage**  
The `WritableRenderedImage` being adapted.

## Constructor Detail

### WritableRenderedImageAdapter

public **WritableRenderedImageAdapter**(`java.awt.image.WritableRenderedImage` im)

Constructs a `WritableRenderedImageAdapter`.

#### Parameters:

im - A `WritableRenderedImage` to be 'wrapped' as a `PlanarImage`.

#### Throws:

`java.lang.IllegalArgumentException` - if im is null.

## Method Detail

### addTileObserver

public final void **addTileObserver**(`java.awt.image.TileObserver` tileObserver)

Add an observer. If the observer is already present, it will receive multiple notifications.

#### Specified by:

`addTileObserver` in interface `java.awt.image.WritableRenderedImage`

#### Parameters:

tileObserver - The `TileObserver` to be added.

#### Throws:

`java.lang.IllegalArgumentException` - if im is null.

---

### removeTileObserver

public final void **removeTileObserver**(`java.awt.image.TileObserver` tileObserver)

Remove an observer. If the observer was not registered, nothing happens. If the observer was registered for multiple notifications, it will now be registered for one fewer.

#### Specified by:

`removeTileObserver` in interface `java.awt.image.WritableRenderedImage`

**Parameters:**

tileObserver - The TileObserver to be removed.

**Throws:**

java.lang.IllegalArgumentException - if im is null.

---

## getWritableTile

```
public final java.awt.image.WritableRaster getWritableTile(int tileX,  
                                                         int tileY)
```

Check out a tile for writing.

The WritableRenderedImage is responsible for notifying all of its TileObservers when a tile goes from having no writers to having one writer.

**Specified by:**

getWritableTile in interface java.awt.image.WritableRenderedImage

**Parameters:**

tileX - The X index of the tile.

tileY - The Y index of the tile.

**Returns:**

The tile as a WritableRaster.

---

## releaseWritableTile

```
public final void releaseWritableTile(int tileX,  
                                       int tileY)
```

Relinquish the right to write to a tile. If the caller continues to write to the tile, the results are undefined. Calls to this method should only appear in matching pairs with calls to getWritableTile(); any other use will lead to undefined results.

The WritableRenderedImage is responsible for notifying all of its TileObservers when a tile goes from having one writer to having no writers.

**Specified by:**

releaseWritableTile in interface java.awt.image.WritableRenderedImage

**Parameters:**

tileX - The X index of the tile.

tileY - The Y index of the tile.

---

## isTileWritable

```
public final boolean isTileWritable(int tileX,  
                                     int tileY)
```

Return whether a tile is currently checked out for writing.

**Specified by:**

isTileWritable in interface java.awt.image.WritableRenderedImage

**Parameters:**

tileX - The X index of the tile.

tileY - The Y index of the tile.

**Returns:**

true if the tile currently has writers.

---

## getWritableTileIndices

```
public final java.awt.Point[] getWritableTileIndices()
```

Return an array of Point objects indicating which tiles are checked out for writing.

**Specified by:**

getWritableTileIndices in interface java.awt.image.WritableRenderedImage

**Returns:**

an array of Points.

---

## hasTileWriters

```
public final boolean hasTileWriters()
```

Return whether any tile is checked out for writing. Semantically equivalent to (getWritableTiles().size() != 0).

**Specified by:**

hasTileWriters in interface java.awt.image.WritableRenderedImage

**Returns:**

true if any tile currently has writers.

---

**setData**

```
public final void setData(java.awt.image.Raster raster)
```

Set a rectangular region of the image to the contents of raster.

**Specified by:**

setData in interface java.awt.image.WritableRenderedImage

**Parameters:**

raster - A Raster.

**Throws:**

java.lang.IllegalArgumentException - if im is null.

---

## Package javax.media.jai.iterator

### Interface Summary

<b><i>RandomIter</i></b>	An iterator that allows random read-only access to any sample within its bounding rectangle.
<b><i>RectIter</i></b>	An iterator for traversing a read-only image in top-to-bottom, left-to-right order.
<b><i>RookIter</i></b>	An iterator for traversing a read-only image using arbitrary up-down and left-right moves.
<b><i>WritableRandomIter</i></b>	An iterator that allows random read/write access to any sample within its bounding rectangle.
<b><i>WritableRectIter</i></b>	An iterator for traversing a read/write image in top-to-bottom, left-to-right order.
<b><i>WritableRookIter</i></b>	An iterator for traversing a read/write image using arbitrary up-down and left-right moves.

### Class Summary

<b>JaiI18N</b>	
<b>RandomIterFactory</b>	A factory class to instantiate instances of the <i>RandomIter</i> and <i>WritableRandomIter</i> interfaces on sources of type <i>Raster</i> , <i>RenderedImage</i> , and <i>WritableRenderedImage</i> .
<b>RectIterFactory</b>	A factory class to instantiate instances of the <i>RectIter</i> and <i>WritableRectIter</i> interfaces on sources of type <i>Raster</i> , <i>RenderedImage</i> , and <i>WritableRenderedImage</i> .
<b>RookIterFactory</b>	A factory class to instantiate instances of the <i>RookIter</i> and <i>WritableRookIter</i> interfaces on sources of type <i>Raster</i> , <i>RenderedImage</i> , and <i>WritableRenderedImage</i> .

## javax.media.jai.iterator Interface RandomIter

**All Known Subinterfaces:**  
WritableRandomIter

---

public abstract interface **RandomIter**

An iterator that allows random read-only access to any sample within its bounding rectangle. This flexibility will generally exact a corresponding price in speed and setup overhead.

The iterator is initialized with a particular rectangle as its bounds, which it is illegal to exceed. This initialization takes place in a factory method and is not a part of the iterator interface itself.

The `getSample()`, `getSampleFloat()`, and `getSampleDouble()` methods are provided to allow read-only access to the source data. The `getPixel()` methods allow retrieval of all bands simultaneously.

An instance of `RandomIter` may be obtained by means of the `RandomIterFactory.create()` method, which returns an opaque object implementing this interface.

**See Also:**

`WritableRandomIter`, `RandomIterFactory`

---

### Method Detail

#### **getSample**

```
public int getSample(int x,  
                    int y,  
                    int b)
```

Returns the specified sample from the image.

**Parameters:**

x - the X coordinate of the desired pixel.  
y - the Y coordinate of the desired pixel.  
b - the band to retrieve.

---

#### **getSampleFloat**

```
public float getSampleFloat(int x,  
                           int y,  
                           int b)
```

Returns the specified sample from the image as a float.

**Parameters:**

x - the X coordinate of the desired pixel.  
y - the Y coordinate of the desired pixel.  
b - the band to retrieve.

---

#### **getSampleDouble**

```
public double getSampleDouble(int x,  
                              int y,  
                              int b)
```

Returns the specified sample from the image as a double.

**Parameters:**

x - the X coordinate of the desired pixel.  
y - the Y coordinate of the desired pixel.  
b - the band to retrieve.

---

#### **getPixel**

```
public int[] getPixel(int x,  
                    int y,  
                    int[] iArray)
```

Returns the samples of the specified pixel from the image in an array of int.

**Parameters:**

x - the X coordinate of the desired pixel.  
y - the Y coordinate of the desired pixel.  
iArray - An optionally preallocated int array.

**Returns:**

the contents of the pixel as an int array.

---

**getPixel**

```
public float[] getPixel(int x,  
                        int y,  
                        float[] fArray)
```

Returns the samples of the specified pixel from the image in an array of float.

**Parameters:**

x - the X coordinate of the desired pixel.  
y - the Y coordinate of the desired pixel.  
fArray - An optionally preallocated float array.

**Returns:**

the contents of the pixel as a float array.

---

**getPixel**

```
public double[] getPixel(int x,  
                        int y,  
                        double[] dArray)
```

Returns the samples of the specified pixel from the image in an array of double.

**Parameters:**

x - the X coordinate of the desired pixel.  
y - the Y coordinate of the desired pixel.  
dArray - An optionally preallocated double array.

**Returns:**

the contents of the pixel as a double array.

---

**done**

```
public void done()
```

Informs the iterator that it may discard its internal data structures. This method should be called when the iterator will no longer be used.

---

## javax.media.jai.iterator Class RandomIterFactory

```
java.lang.Object
|
+-- javax.media.jai.iterator.RandomIterFactory
```

---

public class **RandomIterFactory**  
extends java.lang.Object

A factory class to instantiate instances of the RandomIter and WritableRandomIter interfaces on sources of type Raster, RenderedImage, and WritableRenderedImage.

**See Also:**

RandomIter, WritableRandomIter

---

### Constructor Detail

#### RandomIterFactory

```
private RandomIterFactory()
```

Prevent this class from ever being instantiated.

### Method Detail

#### create

```
public static RandomIter create(java.awt.image.RenderedImage im,  
                                java.awt.Rectangle bounds)
```

Constructs and returns an instance of RandomIter suitable for iterating over the given bounding rectangle within the given RenderedImage source. If the bounds parameter is null, the entire image will be used.

**Parameters:**

im - a read-only RenderedImage source.  
bounds - the bounding Rectangle for the iterator, or null.

**Returns:**

a RandomIter allowing read-only access to the source.

---

#### create

```
public static RandomIter create(java.awt.image.Raster ras,  
                                java.awt.Rectangle bounds)
```

Constructs and returns an instance of RandomIter suitable for iterating over the given bounding rectangle within the given Raster source. If the bounds parameter is null, the entire Raster will be used.

**Parameters:**

ras - a read-only Raster source.  
bounds - the bounding Rectangle for the iterator, or null.

**Returns:**

a RandomIter allowing read-only access to the source.

---

#### createWritable

```
public static WritableRandomIter createWritable(java.awt.image.WritableRenderedImage im,  
                                                  java.awt.Rectangle bounds)
```

Constructs and returns an instance of WritableRandomIter suitable for iterating over the given bounding rectangle within the given WritableRenderedImage source. If the bounds parameter is null, the entire image will be used.

**Parameters:**

im - a WritableRenderedImage source.  
bounds - the bounding Rectangle for the iterator, or null.

**Returns:**

a WritableRandomIter allowing read/write access to the source.

---

## **createWritable**

```
public static WritableRandomIter createWritable(java.awt.image.WritableRaster ras,  
                                              java.awt.Rectangle bounds)
```

Constructs and returns an instance of WritableRandomIter suitable for iterating over the given bounding rectangle within the given WritableRaster source. If the bounds parameter is null, the entire Raster will be used.

**Parameters:**

ras - a WritableRaster source.

bounds - the bounding Rectangle for the iterator, or null.

**Returns:**

a WritableRandomIter allowing read/write access to the source.

---

## javax.media.jai.iterator Interface RectIter

### All Known Subinterfaces:

RookIter, WritableRectIter, WritableRookIter

---

public abstract interface **RectIter**

An iterator for traversing a read-only image in top-to-bottom, left-to-right order. This will generally be the fastest style of iterator, since it does not need to perform bounds checks against the top or left edges of tiles.

The iterator is initialized with a particular rectangle as its bounds, which it is illegal to exceed. This initialization takes place in a factory method and is not a part of the iterator interface itself. Once initialized, the iterator may be reset to its initial state by means of the `startLine()`, `startPixels()`, and `startBands()` methods. Its position may be advanced using the `nextLine()`, `jumpLines()`, `nextPixel()`, `jumpPixels()`, and `nextBand()` methods.

The iterator's position may be tested against the bounding rectangle by means of the `finishedLines()`, `finishedPixels()`, and `finishedBands()` methods, as well as the hybrid methods `nextLineDone()`, `nextPixelDone()`, and `nextBandDone()`.

The `getSample()`, `getSampleFloat()`, and `getSampleDouble()` methods are provided to allow read-only access to the source data. The various source bands may also be accessed in random fashion using the variants that accept a band index. The `getPixel()` methods allow retrieval of all bands simultaneously.

An instance of `RectIter` may be obtained by means of the `RectIterFactory.create()` method, which returns an opaque object implementing this interface.

### See Also:

`WritableRectIter`, `RectIterFactory`

---

## Method Detail

### startLines

public void **startLines()**

Sets the iterator to the first line of its bounding rectangle. The pixel and band offsets are unchanged.

---

### nextLine

public void **nextLine()**

Sets the iterator to the next line of the image. The pixel and band offsets are unchanged. If the iterator passes the bottom line of the rectangles, calls to `get()` methods are not valid.

---

### nextLineDone

public boolean **nextLineDone()**

Sets the iterator to the next line in the image, and returns true if the bottom row of the bounding rectangle has been passed.

---

### jumpLines

public void **jumpLines**(int num)

Jumps downward num lines from the current position. Num may be negative. The pixel and band offsets are unchanged. If the position after the jump is outside of the iterator's bounding box, an `IndexOutOfBoundsException` will be thrown and the position will be unchanged.

#### Throws:

`java.lang.IndexOutOfBoundsException` - if the position goes outside of the iterator's bounding box.

---

### finishedLines

public boolean **finishedLines()**

Returns true if the bottom row of the bounding rectangle has been passed.

---

## startPixels

```
public void startPixels()
```

Sets the iterator to the leftmost pixel of its bounding rectangle. The line and band offsets are unchanged.

---

## nextPixel

```
public void nextPixel()
```

Sets the iterator to the next pixel in image (that is, move rightward). The line and band offsets are unchanged.

---

## nextPixelDone

```
public boolean nextPixelDone()
```

Sets the iterator to the next pixel in the image (that is, move rightward). Returns true if the right edge of the bounding rectangle has been passed. The line and band offsets are unchanged.

---

## jumpPixels

```
public void jumpPixels(int num)
```

Jumps rightward num pixels from the current position. Num may be negative. The line and band offsets are unchanged. If the position after the jump is outside of the iterator's bounding box, an `IndexOutOfBoundsException` will be thrown and the position will be unchanged.

**Throws:**

`java.lang.IndexOutOfBoundsException` - if the position goes outside of the iterator's bounding box.

---

## finishedPixels

```
public boolean finishedPixels()
```

Returns true if the right edge of the bounding rectangle has been passed.

---

## startBands

```
public void startBands()
```

Sets the iterator to the first band of the image. The pixel column and line are unchanged.

---

## nextBand

```
public void nextBand()
```

Sets the iterator to the next band in the image. The pixel column and line are unchanged.

---

## nextBandDone

```
public boolean nextBandDone()
```

Sets the iterator to the next band in the image, and returns true if the max band has been exceeded. The pixel column and line are unchanged.

---

## finishedBands

```
public boolean finishedBands()
```

Returns true if the max band in the image has been exceeded.

---

## getSample

```
public int getSample()
```

Returns the current sample as an integer.

---

## getSample

```
public int getSample(int b)
```

Returns the specified sample of the current pixel as an integer.

**Parameters:**

b - the band index of the desired sample.

---

## getSampleFloat

```
public float getSampleFloat()
```

Returns the current sample as a float.

---

## getSampleFloat

```
public float getSampleFloat(int b)
```

Returns the specified sample of the current pixel as a float.

**Parameters:**

b - the band index of the desired sample.

---

## getSampleDouble

```
public double getSampleDouble()
```

Returns the current sample as a double.

---

## getSampleDouble

```
public double getSampleDouble(int b)
```

Returns the specified sample of the current pixel as a double.

**Parameters:**

b - the band index of the desired sample.

---

## getPixel

```
public int[] getPixel(int[] iArray)
```

Returns the samples of the current pixel from the image in an array of int.

**Parameters:**

iArray - An optionally preallocated int array.

**Returns:**

the contents of the pixel as an int array.

---

## getPixel

```
public float[] getPixel(float[] fArray)
```

Returns the samples of the current pixel from the image in an array of float.

**Parameters:**

fArray - An optionally preallocated float array.

**Returns:**

the contents of the pixel as a float array.

---

## getPixel

```
public double[] getPixel(double[] dArray)
```

Returns the samples of the current pixel from the image in an array of double.

**Parameters:**

dArray - An optionally preallocated double array.

**Returns:**

the contents of the pixel as a double array.

---

## javax.media.jai.iterator Class RectIterFactory

```
java.lang.Object
|
+-- javax.media.jai.iterator.RectIterFactory
```

---

public class **RectIterFactory**  
extends java.lang.Object

A factory class to instantiate instances of the RectIter and WritableRectIter interfaces on sources of type Raster, RenderedImage, and WritableRenderedImage.

**See Also:**

RectIter, WritableRectIter

---

### Constructor Detail

#### RectIterFactory

```
private RectIterFactory()
```

Prevent this class from ever being instantiated.

### Method Detail

#### create

```
public static RectIter create(java.awt.image.RenderedImage im,  
                             java.awt.Rectangle bounds)
```

Constructs and returns an instance of RectIter suitable for iterating over the given bounding rectangle within the given RenderedImage source. If the bounds parameter is null, the entire image will be used.

**Parameters:**

im - a read-only RenderedImage source.  
bounds - the bounding Rectangle for the iterator, or null.

**Returns:**

a RectIter allowing read-only access to the source.

---

#### create

```
public static RectIter create(java.awt.image.Raster ras,  
                             java.awt.Rectangle bounds)
```

Constructs and returns an instance of RectIter suitable for iterating over the given bounding rectangle within the given Raster source. If the bounds parameter is null, the entire Raster will be used.

**Parameters:**

ras - a read-only Raster source.  
bounds - the bounding Rectangle for the iterator, or null.

**Returns:**

a RectIter allowing read-only access to the source.

---

#### createWritable

```
public static WritableRectIter createWritable(java.awt.image.WritableRenderedImage im,  
                                              java.awt.Rectangle bounds)
```

Constructs and returns an instance of WritableRectIter suitable for iterating over the given bounding rectangle within the given WritableRenderedImage source. If the bounds parameter is null, the entire image will be used.

**Parameters:**

im - a WritableRenderedImage source.  
bounds - the bounding Rectangle for the iterator, or null.

**Returns:**

a WritableRectIter allowing read/write access to the source.

---

## **createWritable**

```
public static WritableRectIter createWritable(java.awt.image.WritableRaster ras,  
                                              java.awt.Rectangle bounds)
```

Constructs and returns an instance of WritableRectIter suitable for iterating over the given bounding rectangle within the given WritableRaster source. If the bounds parameter is null, the entire Raster will be used.

**Parameters:**

ras - a WritableRaster source.

bounds - the bounding Rectangle for the iterator, or null.

**Returns:**

a WritableRectIter allowing read/write access to the source.

---

## javax.media.jai.iterator Interface RookIter

**All Known Subinterfaces:**  
WritableRookIter

---

public abstract interface **RookIter**  
extends RectIter

An iterator for traversing a read-only image using arbitrary up-down and left-right moves. This will generally be somewhat slower than a corresponding instance of RectIter, since it must perform bounds checks against the top and left edges of tiles in addition to their bottom and right edges.

The iterator is initialized with a particular rectangle as its bounds, which it is illegal to exceed. This initialization takes place in a factory method and is not a part of the iterator interface itself. Once initialized, the iterator may be reset to its initial state by means of the startLine(), startPixels(), and startBands() methods. As with RectIter, its position may be advanced using the nextLine(), jumpLines(), nextPixel(), jumpPixels(), and nextBand() methods.

In addition, prevLine(), prevPixel(), and prevBand() methods exist to move in the upwards and leftwards directions and to access smaller band indices. The iterator may be set to the far edges of the bounding rectangle by means of the endLines(), endPixels(), and endBands() methods.

The iterator's position may be tested against the bounding rectangle by means of the finishedLines(), finishedPixels(), and finishedBands() methods, as well as the hybrid methods nextLineDone(), prevLineDone(), nextPixelDone(), prevPixelDone(), nextBandDone(), and prevBandDone().

The getSample(), getSampleFloat(), and getSampleDouble() methods are provided to allow read-only access to the source data. The various source bands may also be accessed in random fashion using the variants that accept a band index. The getPixel() methods allow retrieval of all bands simultaneously.

An instance of RookIter may be obtained by means of the RookIterFactory.create() method, which returns an opaque object implementing this interface.

**See Also:**

RectIter, RookIterFactory

---

### Method Detail

#### prevLine

public void **prevLine**()

Sets the iterator to the previous line of the image. The pixel and band offsets are unchanged. If the iterator passes the top line of the rectangle, calls to get() methods are not valid.

---

#### prevLineDone

public boolean **prevLineDone**()

Sets the iterator to the previous line in the image, and returns true if the top row of the bounding rectangle has been passed.

---

#### endLines

public void **endLines**()

Sets the iterator to the last line of its bounding rectangle. The pixel and band offsets are unchanged.

---

#### prevPixel

public void **prevPixel**()

Sets the iterator to the previous pixel in the image (that is, move leftward). The line and band offsets are unchanged.

---

#### prevPixelDone

public boolean **prevPixelDone**()

Sets the iterator to the previous pixel in the image (that is, move leftward). Returns true if the left edge of the bounding rectangle has been passed. The line and band offsets are unchanged.

---

## **endPixels**

`public void endPixels()`

Sets the iterator to the rightmost pixel of its bounding rectangle. The line and band offsets are unchanged.

---

## **prevBand**

`public void prevBand()`

Sets the iterator to the previous band in the image. The pixel column and line are unchanged.

---

## **prevBandDone**

`public boolean prevBandDone()`

Sets the iterator to the previous band in the image, and returns true if the min band has been exceeded. The pixel column and line are unchanged.

---

## **endBands**

`public void endBands()`

Sets the iterator to the last band of the image. The pixel column and line are unchanged.

---

## javax.media.jai.iterator Class RookIterFactory

```
java.lang.Object
|
+-- javax.media.jai.iterator.RookIterFactory
```

---

public class **RookIterFactory**  
extends java.lang.Object

A factory class to instantiate instances of the RookIter and WritableRookIter interfaces on sources of type Raster, RenderedImage, and WritableRenderedImage.

**See Also:**

RookIter, WritableRookIter

---

### Constructor Detail

#### RookIterFactory

```
private RookIterFactory()
```

Prevent this class from ever being instantiated.

### Method Detail

#### create

```
public static RookIter create(java.awt.image.RenderedImage im,  
                             java.awt.Rectangle bounds)
```

Constructs and returns an instance of RookIter suitable for iterating over the given bounding rectangle within the given RenderedImage source. If the bounds parameter is null, the entire image will be used.

**Parameters:**

im - a read-only RenderedImage source.  
bounds - the bounding Rectangle for the iterator, or null.

**Returns:**

a RookIter allowing read-only access to the source.

---

#### create

```
public static RookIter create(java.awt.image.Raster ras,  
                             java.awt.Rectangle bounds)
```

Constructs and returns an instance of RookIter suitable for iterating over the given bounding rectangle within the given Raster source. If the bounds parameter is null, the entire Raster will be used.

**Parameters:**

ras - a read-only Raster source.  
bounds - the bounding Rectangle for the iterator, or null.

**Returns:**

a RookIter allowing read-only access to the source.

---

#### createWritable

```
public static WritableRookIter createWritable(java.awt.image.WritableRenderedImage im,  
                                              java.awt.Rectangle bounds)
```

Constructs and returns an instance of WritableRookIter suitable for iterating over the given bounding rectangle within the given WritableRenderedImage source. If the bounds parameter is null, the entire image will be used.

**Parameters:**

im - a WritableRenderedImage source.  
bounds - the bounding Rectangle for the iterator, or null.

**Returns:**

a WritableRookIter allowing read/write access to the source.

---

## **createWritable**

```
public static WritableRookIter createWritable(java.awt.image.WritableRaster ras,  
                                              java.awt.Rectangle bounds)
```

Constructs and returns an instance of WritableRookIter suitable for iterating over the given bounding rectangle within the given WritableRaster source. If the bounds parameter is null, the entire Raster will be used.

**Parameters:**

ras - a WritableRaster source.

bounds - the bounding Rectangle for the iterator, or null.

**Returns:**

a WritableRookIter allowing read/write access to the source.

---

## javax.media.jai.iterator Interface WritableRandomIter

---

public abstract interface **WritableRandomIter**  
extends **RandomIter**

An iterator that allows random read/write access to any sample within its bounding rectangle. This flexibility will generally exact a corresponding price in speed and setup overhead.

The iterator is initialized with a particular rectangle as its bounds, which it is illegal to exceed. This initialization takes place in a factory method and is not a part of the iterator interface itself.

The `setSample()` and `setPixel()` methods allow individual source samples and whole pixels to be written.

An instance of **RandomIter** may be obtained by means of the `RandomIterFactory.createWritable()` method, which returns an opaque object implementing this interface.

### See Also:

`RandomIter`, `RandomIterFactory`

---

## Method Detail

### setSample

```
public void setSample(int x,  
                      int y,  
                      int b,  
                      int s)
```

Sets the specified sample of the image to an integral value.

#### Parameters:

- x - the X coordinate of the pixel.
  - y - the Y coordinate of the pixel.
  - b - the band to be set.
  - s - the sample's new integral value.
- 

### setSample

```
public void setSample(int x,  
                      int y,  
                      int b,  
                      float s)
```

Sets the specified sample of the image to a float value.

#### Parameters:

- x - the X coordinate of the pixel.
  - y - the Y coordinate of the pixel.
  - b - the band to be set.
  - s - the sample's new float value.
- 

### setSample

```
public void setSample(int x,  
                      int y,  
                      int b,  
                      double s)
```

Sets the specified sample of the image to a double value.

#### Parameters:

- x - the X coordinate of the pixel.
  - y - the Y coordinate of the pixel.
  - b - the band to be set.
  - s - the sample's new double value.
-

## setPixel

```
public void setPixel(int x,  
                    int y,  
                    int[] iArray)
```

Sets a pixel in the image using an int array of samples for input.

**Parameters:**

x - the X coordinate of the pixel.  
y - the Y coordinate of the pixel.  
iArray - the input samples in an int array.

---

## setPixel

```
public void setPixel(int x,  
                    int y,  
                    float[] fArray)
```

Sets a pixel in the image using a float array of samples for input.

**Parameters:**

x - the X coordinate of the pixel.  
y - the Y coordinate of the pixel.  
fArray - the input samples in a float array.

---

## setPixel

```
public void setPixel(int x,  
                    int y,  
                    double[] dArray)
```

Sets a pixel in the image using a float array of samples for input.

**Parameters:**

x - the X coordinate of the pixel.  
y - the Y coordinate of the pixel.  
dArray - the input samples in a double array.

---

## javax.media.jai.iterator Interface WritableRectIter

All Known Subinterfaces:  
WritableRookIter

---

public abstract interface **WritableRectIter**  
extends RectIter

An iterator for traversing a read/write image in top-to-bottom, left-to-right order. This will generally be the fastest style of iterator, since it does not need to perform bounds checks against the top or left edges of tiles.

The iterator is initialized with a particular rectangle as its bounds, which it is illegal to exceed. This initialization takes place in a factory method and is not a part of the iterator interface itself. Once initialized, the iterator may be reset to its initial state by means of the `startLine()`, `startPixels()`, and `startBands()` methods. Its position may be advanced using the `nextLine()`, `jumpLines()`, `nextPixel()`, `jumpPixels()`, and `nextBand()` methods.

The iterator's position may be tested against the bounding rectangle by means of the `finishedLines()`, `finishedPixels()`, and `finishedBands()` methods, as well as the hybrid methods `nextLineDone()`, `nextPixelDone()`, and `nextBandDone()`.

The `getSample()`, `getSampleFloat()`, and `getSampleDouble()` methods are provided to allow read-only access to the source data. The various source bands may also be accessed in random fashion using the variants that accept a band index. The `getPixel()` methods allow retrieval of all bands simultaneously.

`WritableRookIter` adds the ability to alter the source pixel values using the various `setSample()` and `setPixel()` methods.

An instance of `WritableRectIter` may be obtained by means of the `RectIterFactory.createWritable()` method, which returns an opaque object implementing this interface.

**See Also:**

`RectIter`, `RectIterFactory`

---

### Method Detail

#### setSample

```
public void setSample(int s)
```

Sets the current sample to an integral value.

---

#### setSample

```
public void setSample(int b,  
                     int s)
```

Sets the specified sample of the current pixel to an integral value.

---

#### setSample

```
public void setSample(float s)
```

Sets the current sample to a float value.

---

#### setSample

```
public void setSample(int b,  
                     float s)
```

Sets the specified sample of the current pixel to a float value.

---

#### setSample

```
public void setSample(double x)
```

Sets the current sample to a double value.

---

### **setSample**

```
public void setSample(int b,  
                     double s)
```

Sets the specified sample of the current pixel to a double value.

---

### **setPixel**

```
public void setPixel(int[] iArray)
```

Sets all samples of the current pixel to a set of int values.

**Parameters:**

iArray - an int array containing a value for each band.

---

### **setPixel**

```
public void setPixel(float[] fArray)
```

Sets all samples of the current pixel to a set of float values.

**Parameters:**

fArray - a float array containing a value for each band.

---

### **setPixel**

```
public void setPixel(double[] dArray)
```

Sets all samples of the current pixel to a set of double values.

**Parameters:**

dArray - a double array containing a value for each band.

---

## javax.media.jai.iterator Interface WritableRookIter

---

public abstract interface **WritableRookIter**  
extends RookIter, WritableRectIter

An iterator for traversing a read/write image using arbitrary up-down and left-right moves. This will generally be somewhat slower than a corresponding instance of RectIter, since it must perform bounds checks against the top and left edges of tiles in addition to their bottom and right edges.

The iterator is initialized with a particular rectangle as its bounds, which it is illegal to exceed. This initialization takes place in a factory method and is not a part of the iterator interface itself. Once initialized, the iterator may be reset to its initial state by means of the startLine(), startPixels(), and startBands() methods. As with RectIter, its position may be advanced using the nextLine(), jumpLines(), nextPixel(), jumpPixels(), and nextBand() methods.

In addition, prevLine(), prevPixel(), and prevBand() methods exist to move in the upwards and leftwards directions and to access smaller band indices. The iterator may be set to the far edges of the bounding rectangle by means of the endLines(), endPixels(), and endBands() methods.

The iterator's position may be tested against the bounding rectangle by means of the finishedLines(), finishedPixels(), and finishedBands() methods, as well as the hybrid methods nextLineDone(), prevLineDone(), nextPixelDone(), prevPixelDone(), nextBandDone(), and prevBandDone().

The getSample(), getSampleFloat(), and getSampleDouble() methods are provided to allow read-only access to the source data. The various source bands may also be accessed in random fashion using the variants that accept a band index. The getPixel() methods allow retrieval of all bands simultaneously.

WritableRookIter adds the ability to alter the source pixel values using the various setSample() and setPixel() methods. These methods are inherited from the WritableRectIter interface unchanged.

An instance of WritableRookIter may be obtained by means of the RookIterFactory.createWritable() method, which returns an opaque object implementing this interface.

Note that a WritableRookIter inherits multiply from RookIter and WritableRectIter, and so may be passed into code expecting either interface. WritableRookIter in fact adds no methods not found in one of its parent interfaces.

## Package javax.media.jai.operator

Class Summary	
<b>AbsoluteDescriptor</b>	An OperationDescriptor describing the "Absolute" operation.
<b>AddCollectionDescriptor</b>	An OperationDescriptor describing the "AddCollection" operation.
<b>AddConstDescriptor</b>	An OperationDescriptor describing the "AddConst" operation.
<b>AddConstToCollectionDescriptor</b>	An OperationDescriptor describing the "AddConstToCollection" operation.
<b>AddDescriptor</b>	An OperationDescriptor describing the "Add" operation.
<b>AffineDescriptor</b>	An OperationDescriptor describing the "Affine" operation.
<b>AffinePropertyGenerator</b>	This property generator computes the properties for the operation "Affine" dynamically.
<b>AndConstDescriptor</b>	An OperationDescriptor describing the "AndConst" operation.
<b>AndDescriptor</b>	An OperationDescriptor describing the "And" operation.
<b>AWTImageDescriptor</b>	An OperationDescriptor describing the "AWTImage" operation.
<b>BandCombineDescriptor</b>	An OperationDescriptor describing the "BandCombine" operation.
<b>BandSelectDescriptor</b>	An OperationDescriptor describing the "BandSelect" operation.
<b>BMPDescriptor</b>	An OperationDescriptor describing the "BMP" operation.
<b>BorderDescriptor</b>	An OperationDescriptor describing the "Border" operation.
<b>BoxFilterDescriptor</b>	An OperationDescriptor describing the "BoxFilter" operation.
<b>ClampDescriptor</b>	An OperationDescriptor describing the "Clamp" operation.
<b>ColorConvertDescriptor</b>	An OperationDescriptor describing the "ColorConvert" operation.
<b>CompositeDescriptor</b>	An OperationDescriptor describing the "Composite" operation.
<b>ConjugateDescriptor</b>	An OperationDescriptor describing the "Conjugate" operation.
<b>ConjugatePropertyGenerator</b>	This property generator computes the properties for the operation "Conjugate" dynamically.
<b>ConstantDescriptor</b>	An OperationDescriptor describing the "Constant" operation.
<b>ConvolveDescriptor</b>	An OperationDescriptor describing the "Convolve" operation.
<b>CropDescriptor</b>	An OperationDescriptor describing the "Crop" operation.
<b>DCTDescriptor</b>	An OperationDescriptor describing the "DCT" operation.
<b>DFTDescriptor</b>	An OperationDescriptor describing the "DFT" operation.
<b>DFTPropertyGenerator</b>	This property generator computes the properties for the operation "DFT" dynamically.
<b>DivideByConstDescriptor</b>	An OperationDescriptor describing the "DivideByConst" operation.
<b>DivideComplexDescriptor</b>	An OperationDescriptor describing the "DivideComplex" operation.
<b>DivideComplexPropertyGenerator</b>	This property generator computes the properties for the operation "DivideComplex" dynamically.
<b>DivideDescriptor</b>	An OperationDescriptor describing the "Divide" operation.

<b>DivideIntoConstDescriptor</b>	An OperationDescriptor describing the "DivideIntoConst" operation.
<b>EncodeDescriptor</b>	An OperationDescriptor describing the "Encode" operation.
<b>ErrorDiffusionDescriptor</b>	An OperationDescriptor describing the "ErrorDiffusion" operation.
<b>ExpDescriptor</b>	An OperationDescriptor describing the "Exp" operation.
<b>ExtremaDescriptor</b>	An OperationDescriptor describing the "Extrema" operation.
<b>FileLoadDescriptor</b>	An OperationDescriptor describing the "FileLoad" operation.
<b>FileStoreDescriptor</b>	An OperationDescriptor describing the "FileStore" operation.
<b>FormatDescriptor</b>	An OperationDescriptor describing the "Format" operation.
<b>FPXDescriptor</b>	An OperationDescriptor describing the "FPX" operation.
<b>GIFDescriptor</b>	An OperationDescriptor describing the "GIF" operation.
<b>GradientMagnitudeDescriptor</b>	An OperationDescriptor describing the "GradientMagnitude" operation.
<b>HistogramDescriptor</b>	An OperationDescriptor describing the "Histogram" operation.
<b>IDCTDescriptor</b>	An OperationDescriptor describing the "IDCT" operation.
<b>IDFTDescriptor</b>	An OperationDescriptor describing the "IDFT" operation.
<b>IDFTPropertyGenerator</b>	This property generator computes the properties for the operation "IDFT" dynamically.
<b>IIPDescriptor</b>	An OperationDescriptor describing the "IIP" operation.
<b>IIPResolutionDescriptor</b>	An OperationDescriptor describing the "IIPResolution" operation.
<b>ImageFunctionDescriptor</b>	An OperationDescriptor describing the "ImageFunction" operation.
<b>ImageFunctionPropertyGenerator</b>	This property generator computes the properties for the operation "ImageFunction" dynamically.
<b>InvertDescriptor</b>	An OperationDescriptor describing the "Invert" operation.
<b>JaiI18N</b>	
<b>JPEGDescriptor</b>	An OperationDescriptor describing the "JPEG" operation.
<b>LogDescriptor</b>	An OperationDescriptor describing the "Log" operation.
<b>LookupDescriptor</b>	An OperationDescriptor describing the "Lookup" operation.
<b>MagnitudeDescriptor</b>	An OperationDescriptor describing the "Magnitude" operation.
<b>MagnitudePropertyGenerator</b>	This property generator computes the properties for the operation "Magnitude" dynamically.
<b>MagnitudeSquaredDescriptor</b>	An OperationDescriptor describing the "MagnitudeSquared" operation.
<b>MagnitudeSquaredPropertyGenerator</b>	This property generator computes the properties for the operation "MagnitudeSquared" dynamically.
<b>MatchCDFDescriptor</b>	An OperationDescriptor describing the "MatchCDF" operation.
<b>MaxDescriptor</b>	An OperationDescriptor describing the "Max" operation.
<b>MeanDescriptor</b>	An OperationDescriptor describing the "Mean" operation.
<b>MedianFilterDescriptor</b>	An OperationDescriptor describing the "MedianFilter" operation.
<b>MinDescriptor</b>	An OperationDescriptor describing the "Min" operation.

<b>MultiplyComplexDescriptor</b>	An OperationDescriptor describing the "MultiplyComplex" operation.
<b>MultiplyComplexPropertyGenerator</b>	This property generator computes the properties for the operation "MultiplyComplex" dynamically.
<b>MultiplyConstDescriptor</b>	An OperationDescriptor describing the "MultiplyConst" operation.
<b>MultiplyDescriptor</b>	An OperationDescriptor describing the "Multiply" operation.
<b>NotDescriptor</b>	An OperationDescriptor describing the "Not" operation.
<b>OrConstDescriptor</b>	An OperationDescriptor describing the "OrConst" operation.
<b>OrderedDitherDescriptor</b>	An OperationDescriptor describing the "OrderedDither" operation.
<b>OrDescriptor</b>	An OperationDescriptor describing the "Or" operation.
<b>OverlayDescriptor</b>	An OperationDescriptor describing the "Overlay" operation.
<b>PatternDescriptor</b>	An OperationDescriptor describing the "Pattern" operation.
<b>PeriodicShiftDescriptor</b>	An OperationDescriptor describing the "PeriodicShift" operation.
<b>PhaseDescriptor</b>	An OperationDescriptor describing the "Phase" operation.
<b>PhasePropertyGenerator</b>	This property generator computes the properties for the operation "Phase" dynamically.
<b>PiecewiseDescriptor</b>	An OperationDescriptor describing the "Piecewise" operation.
<b>PNGDescriptor</b>	An OperationDescriptor describing the "PNG" operation.
<b>PNMDescriptor</b>	An OperationDescriptor describing the "PNM" operation.
<b>PolarToComplexDescriptor</b>	An OperationDescriptor describing the "PolarToComplex" operation.
<b>PolarToComplexPropertyGenerator</b>	This property generator computes the properties for the operation "PolarToComplex" dynamically.
<b>RenderableDescriptor</b>	An OperationDescriptor describing the "Renderable" operation.
<b>RescaleDescriptor</b>	An OperationDescriptor describing the "Rescale" operation.
<b>RotateDescriptor</b>	An OperationDescriptor describing the "Rotate" operation.
<b>RotatePropertyGenerator</b>	This property generator computes the properties for the operation "Rotate" dynamically.
<b>ScaleDescriptor</b>	An OperationDescriptor describing the "Scale" operation.
<b>ScalePropertyGenerator</b>	This property generator computes the properties for the operation "Scale" dynamically.
<b>ShearDescriptor</b>	An OperationDescriptor describing the "Shear" operation.
<b>ShearPropertyGenerator</b>	This property generator computes the properties for the operation "Shear" dynamically.
<b>StreamDescriptor</b>	An OperationDescriptor describing the "Stream" operation.
<b>SubtractConstDescriptor</b>	An OperationDescriptor describing the "SubtractConst" operation.
<b>SubtractDescriptor</b>	An OperationDescriptor describing the "Subtract" operation.
<b>SubtractFromConstDescriptor</b>	An OperationDescriptor describing the "SubtractFromConst" operation.
<b>ThresholdDescriptor</b>	An OperationDescriptor describing the "Threshold" operation.
<b>TIFFDescriptor</b>	An OperationDescriptor describing the "TIFF" operation.

<b>TranslateDescriptor</b>	An <code>OperationDescriptor</code> describing the "Translate" operation.
<b>TranslatePropertyGenerator</b>	This property generator computes the properties for the operation "Translate" dynamically.
<b>TransposeDescriptor</b>	An <code>OperationDescriptor</code> describing the "Transpose" operation.
<b>TransposePropertyGenerator</b>	This property generator computes the properties for the operation "Transpose" dynamically.
<b>URLDescriptor</b>	An <code>OperationDescriptor</code> describing the "URL" operation.
<b>WarpDescriptor</b>	An <code>OperationDescriptor</code> describing the "Warp" operation.
<b>WarpPropertyGenerator</b>	This property generator computes the properties for the operation "Warp" dynamically.
<b>XorConstDescriptor</b>	An <code>OperationDescriptor</code> describing the "XorConst" operation.
<b>XorDescriptor</b>	An <code>OperationDescriptor</code> describing the "Xor" operation.

---

## javax.media.jai.operator

### Class AWTImageDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.AWTImageDescriptor
```

---

public class **AWTImageDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "AWTImage" operation.

The AWTImage operation converts a standard `java.awt.Image` into a rendered image. By default, the width and height of the image are the same as the original AWT image. The sample model and color model are set according to the AWT image data.

#### Resource List

Name	Value
GlobalName	AWTImage
LocalName	AWTImage
Vendor	com.sun.media.jai
Description	Converts a <code>java.awt.Image</code> into a rendered image.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/AWTImageDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/AWTImageDescriptor.html</a>
Version	1.0
arg0Desc	The AWT image to be converted.

#### Parameter List

Name	Class Type	Default Value
awtImage	<code>java.awt.Image</code>	NO_PARAMETER_DEFAULT

```

Constructor.

---

## javax.media.jai.operator

### Class AbsoluteDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.AbsoluteDescriptor
```

---

public class **AbsoluteDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Absolute" operation.

The "Absolute" operation takes a single rendered or renderable source image, and computes the mathematical absolute value of each pixel:

```
if (src[x][y][b] < 0) {
    dst[x][y][b] = -src[x][y][b];
} else {
    dst[x][y][b] =  src[x][y][b];
}
```

For signed integral data types, the smallest value of the data type does not have a positive counterpart; such values will be left unchanged. This behavior parallels that of the Java unary minus operator (see *The Java Language Specification*, section 15.14.4).

#### Resource List

Name	Value
GlobalName	Absolute
LocalName	Absolute
Vendor	com.sun.media.jai
Description	Replaces the pixel values of an image by their absolute values.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/AbsoluteDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/AbsoluteDescriptor.html</a>
Version	1.0

No parameters are needed for the "Absolute" operation.

### Method Detail

## **isRenderableSupported**

public boolean **isRenderableSupported**()

Returns true since renderable operation is supported.

### **Overrides:**

isRenderableSupported in class OperationDescriptorImpl

---

## javax.media.jai.operator

### Class AddCollectionDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.AddCollectionDescriptor
```

---

public class **AddCollectionDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "AddCollection" operation.

The AddCollection operation takes a collection of rendered source images, and adds every set of pixels, one from each source image of the corresponding position and band. No additional parameters are required.

There is no restriction on the actual class type used to represent the source collection, but each element of the collection must be an instance of `RenderedImage`. The number of images in the collection may vary from 2 to n. The source images may have different numbers of bands and data types.

By default, the destination image bounds are the intersection of all of the source image bounds. If any of the two sources are completely disjoint, the destination will have a width and a height of 0. The number of bands of the destination image is equal to the minimum number of bands of all the sources, and the data type is the biggest data type of all the sources. If the result of the operation underflows/overflows the minimum/maximum value supported by the destination data type, then it will be clamped to the minimum/maximum value respectively.

The destination pixel values are defined by the pseudocode:

```
dst[x][y][b] = 0;
for (int i = 0; i < numSources; i++) {
    dst[x][y][b] += srcs[i][x][y][b];
}
```

#### Resource List

Name	Value
GlobalName	AddCollection
LocalName	AddCollection
Vendor	com.sun.media.jai
Description	Adds a collection of rendered images.

validateSources in class OperationDescriptorImpl

---

## javax.media.jai.operator

### Class AddConstDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.AddConstDescriptor
```

---

public class **AddConstDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "AddConst" operation.

The AddConst operation takes one rendered or renderable source image and an array of double constants, and adds a constant to every pixel of its corresponding band of the source. If the number of constants supplied is less than the number of bands of the destination, then the constant from entry 0 is applied to all the bands. Otherwise, a constant from a different entry is applied to each band.

By default, the destination image bound, data type, and number of bands are the same as the source image. If the result of the operation underflows/overflows the minimum/maximum value supported by the destination data type, then it will be clamped to the minimum/maximum value respectively.

The destination pixel values are defined by the pseudocode:

```
if (constants.length < dstNumBands) {
    dst[x][y][b] = src[x][y][b] + constants[0];
} else {
    dst[x][y][b] = src[x][y][b] + constants[b];
}
```

## Constructor Detail

### AddConstDescriptor

```
public AddConstDescriptor()
```

Constructor.

## Method Detail

### isRenderableSupported

```
public boolean isRenderableSupported()
```

Returns true since renderable operation is supported.

**Overrides:**

isRenderableSupported in class OperationDescriptorImpl

---

### validateParameters

```
protected boolean validateParameters(java.awt.image.renderable.ParameterBlock args,  
                                     java.lang.StringBuffer message)
```

Validates the input parameter.

In addition to the standard checks performed by the superclass method, this method checks that the length of the "constants" array is at least 1.

**Overrides:**

validateParameters in class OperationDescriptorImpl

---

## javax.media.jai.operator

### Class AddConstToCollectionDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.AddConstToCollectionDescriptor
```

---

public class **AddConstToCollectionDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "AddConstToCollection" operation.

The `AddConstToCollection` operation takes a collection of rendered images and an array of double constants, and for each rendered image in the collection adds a constant to every pixel of its corresponding band. If the number of constants supplied is less than the number of bands of a source image then the same constant from entry 0 is applied to all the bands. Otherwise, a constant from a different entry is applied to each band.

The operation will attempt to store the result images in the same collection class as that of the source images. If a new instance of the source collection class can not be created, then the operation will store the result images in a `java.util.Vector`. There will be the same number of images in the output collection as in the source collection.

## javax.media.jai.operator

### Class AddDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.AddDescriptor
```

---

public class **AddDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "Add" operation.

The Add operation takes two rendered or renderable source images, and adds every pair of pixels, one from each source image of the corresponding position and band. No additional parameters are required.

The two source images may have different numbers of bands and data types. By default, the destination image bounds are the intersection of the two source image bounds. If the sources don't intersect, the destination will have a width and height of 0.

The default number of bands of the destination image is equal to the smallest number of bands of the sources, and the data type is the smallest data type with sufficient range to cover the range of both source data types (not necessarily the range of their sums).

As a special case, if one of the source images has N bands ( $N > 1$ ), the other source has 1 band, and an `ImageLayout` hint is provided containing a destination `SampleModel` with K bands ( $1 < K \leq N$ ), then the single band of the 1-banded source is added to each of the first K bands of the N-band source.

If the result of the operation underflows/overflows the minimum/maximum value supported by the destination data type, then it will be clamped to the minimum/maximum value respectively.

The destination pixel values are defined by the pseudocode:

```
dst[x][y][dstBand] = clamp(srcs[0][x][y][src0Band] +
                             srcs[1][x][y][src1Band]);
```

## javax.media.jai.operator

### Class AffineDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.AffineDescriptor
```

---

public class **AffineDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Affine" operation.

The Affine operation performs (possibly filtered) affine mapping on a rendered or renderable source image.

The relationship between the source and the destination pixels is defined as follows. For each pixel (x, y) of the destination, the source value at the fractional subpixel position (x', y') is constructed by means of an Interpolation object and written to the destination. The mapping between the destination pixel (x, y) and the source position (x', y') is given by:

$$\begin{aligned}x' &= m[0][0] * x + m[0][1] * y + m[0][2] \\y' &= m[1][0] * x + m[1][1] * y + m[1][2]\end{aligned}$$

where m is a 3x2 transform matrix that inverts the matrix supplied as the "transform" argument.

When interpolations which require padding the source such as Bilinear or Bicubic interpolation are specified, the source needs to be extended such that it has the extra pixels needed to compute all the destination pixels. This extension is performed via the BorderExtender class. The type of Border Extension can be specified as a RenderingHint to the JAI.create method.

If no BorderExtender is specified (is null), the source will not be extended. The transformed image size is still the same as if the source had been extended. However, since there is insufficient source to compute all the destination pixels, only that subset of the destination image's pixels which can be computed will be written in the destination. The rest of the destination will be set to zeros.

"Affine" defines a PropertyGenerator that performs an identical transformation on the "ROI" property of the source image, which can be retrieved by calling the getProperty method with "ROI" as the property name.

```

---

class **AffinePropertyGenerator**  
extends java.lang.Object  
implements PropertyGenerator  
This property generator computes the properties for the operation "Affine" dynamically.

---

### Constructor Detail

**AffinePropertyGenerator**  
public **AffinePropertyGenerator**()  
Constructor.

### Method Detail

**getPropertyNames**  
public java.lang.String[] **getPropertyNames**()  
Returns the valid property names for the operation "Affine".  
**Specified by:**  
getPropertyNames in interface PropertyGenerator

---

**getProperty**  
public java.lang.Object **getProperty**(java.lang.String name,  
RenderedOp op)  
Returns the specified property.  
**Specified by:**  
getProperty in interface PropertyGenerator  
**Parameters:**  
name - Property name.

---

**getProperty**  
public java.lang.Object **getProperty**(java.lang.String name,  
RenderableOp op)  
Returns null.  
**Specified by:**  
getProperty in interface PropertyGenerator  
**Parameters:**  
name - Property name.

---

## javax.media.jai.operator Class AndConstDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.AndConstDescriptor
```

---

public class **AndConstDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "AndConst" operation.

This operation takes one rendered or renderable image and an array of integer constants, and performs a bit-wise logical "and" between every pixel in the same band of the source and the constant from the corresponding array entry. If the number of constants supplied is less than the number of bands of the destination, then the constant from entry 0 is applied to all the bands. Otherwise, a constant from a different entry is applied to each band.

The source image must have an integral data type. By default, the destination image bound, data type, and number of bands are the same as the source image.

The following matrix defines the logical "and" operation.

Logical "and"

src	const	Result
0	0	0
0	1	0
1	0	0
1	1	1

The destination pixel values are defined by the pseudocode:

```
if (constants.length < dstNumBands) {
    dst[x][y][b] = srcs[x][y][b] & constants[0];
} else {
    dst[x][y][b] = srcs[x][y][b] & constants[b];
}
```

### Resource List

public boolean validateArguments(java.awt.image.renderable.ParameterBlock args,  
                                 java.lang.StringBuffer message)
```

Validates the input source and parameter.

In addition to the standard checks performed by the superclass method, this method checks that the source image has an integral data type and that "constants" has length at least 1.

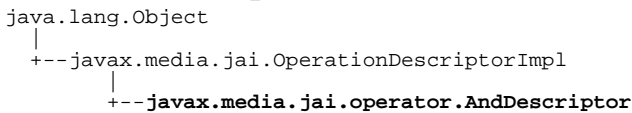

**Overrides:**

validateArguments in class OperationDescriptorImpl

---

# javax.media.jai.operator

## Class AndDescriptor

public class **AndDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "And" operation.

The And operation takes two source images, and performs a bit-wise logical "and" on every pair of pixels, one from each source image, of the corresponding position and band. No additional parameters are required.

Both source images must have integral data types. The two data types may be different.

Unless altered by an ImageLayout hint, the destination image bound is the intersection of the two source image bounds. If the two sources don't intersect, the destination will have a width and height of 0. The number of bands of the destination image is equal to the lesser number of bands of the sources, and the data type is the smallest data type with sufficient range to cover the range of both source data types.

The following matrix defines the logical "and" operation.

Logical "and"

src1	src2	Result
1	1	1
1	0	0
0	1	0
0	0	0

The destination pixel values are defined by the pseudocode:

```
dst[x][y][b] = srcs[0][x][y][b] & srcs[1][x][y][b];
```

### Class BMPDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.BMPDescriptor
```

---

public class **BMPDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "BMP" operation.

The "BMP" operation reads a standard BMP input stream. The "BMP" operation currently reads Version2, Version3 and some of the Version 4 images, as defined in the Microsoft Windows BMP file format.

Version 4 of the BMP format allows for the specification of alpha values, gamma values and CIE colorspace. These are not currently handled, but the relevant properties are emitted, if they are available from the BMP image file.

**The classes in the `com.sun.media.jai.codec` package are not a committed part of the JAI API. Future releases of JAI will make use of new classes in their place. This class will change accordingly.**

#### Resource List

### Class BandCombineDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.BandCombineDescriptor
```

---

public class **BandCombineDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "BandCombine" operation.

The BandCombining operation computes a set of arbitrary linear combinations of the bands of a rendered or renderable source image, using a specified matrix. The matrix must a number of rows equal to the number of desired destination bands and a number of columns equal to the number of source bands plus one. In other words, the array may be constructed using the syntax:

```
double[][] matrix = new double[destBands][sourceBands + 1];
```

The number of source bands used to determine the matrix dimensions is given by `OpImage.getExpandedNumBands(source.getSampleModel(), source.getColorModel())`. In particular, if the source image has an `IndexColorModel`, the number of bands is given by the `ColorModel`'s number of output components.

If the result of the computation underflows/overflows the minimum/maximum value supported by the destination image, then it will be clamped to the minimum/maximum value respectively.

#### Resource List

## javax.media.jai.operator

### Class BandSelectDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.BandSelectDescriptor
```

---

public class **BandSelectDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "BandSelect" operation.

The BandSelect operation chooses N bands from a rendered or renderable source image and copies the pixel data of these bands to the destination image in the order specified. The `bandIndices` parameter specifies the source band indices, and its size (`bandIndices.length`) determines the number of bands of the destination image. The destination image may have any number of bands, and a particular band of the source image may be repeated in the destination image by specifying it multiple times in the `bandIndices` parameter.

Each of the `bandIndices` value should be a valid band index number of the source image. For example, if the source only has two bands, then 1 is a valid band index, but 3 is not. The first band is numbered 0.

The destination pixel values are defined by the pseudocode:

```
dst[x][y][b] = src[x][y][bandIndices[b]];
```

#### Resource List

Name	Value
GlobalName	BandSelect
LocalName	BandSelect
Vendor	com.sun.media.jai

## javax.media.jai.operator

### Class BorderDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.BorderDescriptor
```

---

public class **BorderDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Border" operation.

The Border operation adds a border around a rendered image. The size of the border is specified in pixels by the left, right, top, and bottom padding parameters, corresponding to the four sides of the source image. These paddings may not be less than 0.

The pixel values of the added border area may be set in the following ways using the constants defined in this class:

- it may be extended with zeros (BORDER\_ZERO\_FILL);
- it may be extended with a constant set of values (BORDER\_CONST\_FILL);
- it may be created by reflection about the edges of the image (BORDER\_REFLECT); or,
- it may be extended by "wrapping" the image plane toroidally, that is, joining opposite edges of the image (BORDER\_WRAP).

When choosing the BORDER\_CONST\_FILL option, an array of constants must be supplied. The array must have at least one element, in which case this same constant is applied to all destination image bands. Alternatively, it may have a different constant entry for each corresponding band. For all other border types, this constants parameter may be null.

#### Resource List

## Method Detail

### getParamMinValue

public java.lang.Number **getParamMinValue**(int index)

Returns the minimum legal value of a specified numeric parameter for this operation.

**Overrides:**

getParamMinValue in class OperationDescriptorImpl

### getParamMaxValue

public java.lang.Number **getParamMaxValue**(int index)

Returns the maximum legal value of a specified numeric parameter for this operation.

**Overrides:**

getParamMaxValue in class OperationDescriptorImpl

### validateParameters

protected boolean **validateParameters**(java.awt.image.renderable.ParameterBlock args,  
java.lang.StringBuffer msg)

Validates input parameters.

In addition to the standard checks performed by the superclass method, this method checks that if "type" is equal to BORDER\_CONST\_FILL, "constants" must not a non-null instance of double[ ] of length at least 1.

**Overrides:**

validateParameters in class OperationDescriptorImpl

---

## javax.media.jai.operator Class BoxFilterDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.BoxFilterDescriptor
```

---

```
public class BoxFilterDescriptor
extends OperationDescriptorImpl
```

An `OperationDescriptor` describing the "BoxFilter" operation.

The "BoxFilter" operation determines the intensity of a pixel in an image by averaging the source pixels within a rectangular area around the pixel. This is a special case of the convolution operation, in which each source pixel contributes the same weight to the destination pixel. The pixel values of the destination image are defined by the pseudocode:

```
int count = width * height; // # of pixels in the box
for (int b = 0; b < numBands; b++) {
    int total = 0;
    for (int j = -yKey; j < -yKey + height; j++) {
        for (int i = -xKey; i < -xKey + width; i++) {
            total += src[x+i][y+j][b];
        }
    }
    dst[x][y][b] = (total + count/2) / count; // round
}
```

Convolution, like any neighborhood operation, leaves a band of pixels around the edges undefined. For example, for a 3x3 kernel only four kernel elements and four source pixels contribute to the convolution pixel at the corners of the source image. Pixels that do not allow the full kernel to be applied to the source are not included in the destination image. A "Border" operation may be used to add an appropriate border to the source image in order to avoid shrinkage of the image boundaries.

The kernel may not be bigger in any dimension than the image data.

## javax.media.jai.operator Class ClampDescriptor

```
java.lang.Object
|
+--javax.media.jai.OperationDescriptorImpl
|
+--javax.media.jai.operator.ClampDescriptor
```

---

public class **ClampDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Clamp" operation.

The Clamp operation takes one rendered or renderable source image, and sets all the pixels whose value is below a "low" value to that low value and all the pixels whose value is above a "high" value to that high value. The pixels whose value is between the "low" value and the "high" value are left unchanged.

A different set of "low" and "high" values may be applied to each band of the source image, or the same set of "low" and "high" values may be applied to all bands of the source. If the number of "low" and "high" values supplied is less than the number of bands of the source, then the values from entry 0 are applied to all the bands. Each "low" value must be less than or equal to its corresponding "high" value.

The destination pixel values are defined by the pseudocode:

```
lowVal = (low.length < dstNumBands) ?
         low[0] : low[b];
highVal = (high.length < dstNumBands) ?
         high[0] : high[b];

if (src[x][y][b] < lowVal) {
    dst[x][y][b] = lowVal;
} else if (src[x][y][b] > highVal) {
    dst[x][y][b] = highVal;
} else {
    dst[x][y][b] = src[x][y][b];
}
```

## javax.media.jai.operator

### Class ColorConvertDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.ColorConvertDescriptor
```

---

public class **ColorConvertDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "ColorConvert" operation.

The ColorConvert operation performs a pixel-by-pixel color conversion of the data in a rendered or renderable source image.

The data are treated as having no alpha channel, i.e., all bands are color bands. The color space of the source image is specified by the `ColorSpace` object of the source image `ColorModel` which must not be null.

Integral data are assumed to occupy the full range of the respective data type; floating point data are assumed to be normalized to the range [0.0,1.0].

By default, the destination image bounds, data type, and number of bands are the same as those of the source image.

## javax.media.jai.operator Class CompositeDescriptor

```
java.lang.Object
|
+--javax.media.jai.OperationDescriptorImpl
|
+--javax.media.jai.operator.CompositeDescriptor
```

---

public class **CompositeDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Composite" operation.

The "Composite" operation combines two images based on their alpha values at each pixel. It is done on a per-band basis, and the two source images are expected to have the same number of bands and the same data type. The destination image has the same data type as the two sources.

The `destAlpha` parameter indicates if the destination image should have an extra alpha channel. If this parameter is set to `NO_DESTINATION_ALPHA`, then the destination image does not include an alpha band, and it should have the same number of bands as the two source images. If it is set to `DESTINATION_ALPHA_FIRST`, then the destination image has one extra band than the source images, which represents the result alpha channel, and this band is the first band (band 0) of the destination. If it is set to `DESTINATION_ALPHA_LAST`, then the destination image also has the extra alpha channel, but this band is the last band of the destination.

The destination pixel values may be viewed as representing a fractional pixel coverage or transparency factor. Specifically, Composite implements the Porter-Duff "over" rule (see *Computer Graphics*, July 1984 pp. 253-259), in which the output color of a pixel with source value/alpha tuples  $(A, a)$  and  $(B, b)$  is given by  $a*A + (1 - a)*(b*B)$ . The output alpha value is given by  $a + (1 - a)*b$ . For premultiplied sources tuples  $(a*A, a)$  and  $(b*B, b)$ , the premultiplied output value is simply  $(a*A) + (1 - a)*(b*B)$ .

The color channels of the two source images are supplied via `source1` and `source2`. The two sources must be either both pre-multiplied by alpha or not. Alpha channel should not be included in `source1` and `source2`.

The alpha channel of the first source images must be supplied via the `source1Alpha` parameter. This parameter may not be null. The alpha channel of the second source image may be supplied via the `source2Alpha` parameter. This parameter may be null, in which case the second source is considered completely opaque. The alpha images should be single-banded, and have the same data type as well as dimensions as their corresponding source images.

The `alphaPremultiplied` parameter indicates whether or not the supplied alpha image is premultiplied to both the source images. It also indicates whether the destination image color channels have the alpha values multiplied to the pixel color values.

The destination image is the combination of the two source images. It has the color channels, and if specified, one additional alpha channel (the band index depends on the value of the `destAlpha` parameter). Whether alpha value is pre-multiplied to the color channels also depend on the value of `alphaPremultiplied` (pre-multiplied if true).

### Resource List

---

#### getParamMaxValue

public java.lang.Number **getParamMaxValue**(int index)  
Returns the maximum legal value of a specified numeric parameter for this operation.  
**Overrides:**  
getParamMaxValue in class OperationDescriptorImpl

---

## javax.media.jai.operator

### Class ConjugateDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.ConjugateDescriptor
```

---

public class **ConjugateDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "Conjugate" operation.

The Conjugate operation negates the imaginary components of pixel values of a rendered or renderable source image containing complex data. The source image must contain an even number of bands with the even-indexed bands (0, 2, ...) representing the real and the odd-indexed bands (1, 3, ...) the imaginary parts of each pixel. The destination image similarly contains an even number of bands with the same interpretation and with contents defined by:

```
dst[x][y][2*k]   = src[x][y][2*k];
dst[x][y][2*k+1] = -src[x][y][2*k+1];
```

where the index  $k$  varies from zero to one less than the number of complex components in the destination image.

"Conjugate" defines a `PropertyGenerator` that sets the "COMPLEX" property of the image to `java.lang.Boolean.TRUE`, which may be retrieved by calling the `getProperty()` method with "COMPLEX" as the property name.

#### Resource List

Name	Value
GlobalName	Conjugate
LocalName	Conjugate
Vendor	com.sun.media.jai
Description	Computes the complex conjugate of a complex image.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/ConjugateDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/ConjugateDescriptor.html</a>
Version	1.0

No parameters are needed for the "Conjugate" operation.

public boolean **isRenderableSupported**()

Returns true since renderable operation is supported.

**Overrides:**

isRenderableSupported in class OperationDescriptorImpl

---

## **getPropertyGenerators**

public PropertyGenerator[] **getPropertyGenerators**()

Returns an array of PropertyGenerators implementing property inheritance for the "Conjugate" operation.

**Returns:**

An array of property generators.

**Overrides:**

getPropertyGenerators in class OperationDescriptorImpl

---

## **validateSources**

protected boolean **validateSources**(java.awt.image.renderable.ParameterBlock args,  
java.lang.StringBuffer msg)

Validates the input sources.

In addition to the standard checks performed by the superclass method, this method checks that the source image has an even number of bands.

**Overrides:**

validateSources in class OperationDescriptorImpl

---

## javax.media.jai.operator Class ConjugatePropertyGenerator

```
java.lang.Object
|
+-- javax.media.jai.operator.ConjugatePropertyGenerator
```

---

class **ConjugatePropertyGenerator**

extends java.lang.Object

implements PropertyGenerator

This property generator computes the properties for the operation "Conjugate" dynamically.

---

### Constructor Detail

#### ConjugatePropertyGenerator

```
public ConjugatePropertyGenerator()
```

Constructor.

### Method Detail

#### getPropertyNames

```
public java.lang.String[] getPropertyNames()
```

Returns the valid property names for the operation "Conjugate".

**Specified by:**

getPropertyNames in interface PropertyGenerator

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,  
                                     RenderedOp op)
```

Returns the specified property.

**Specified by:**

getProperty in interface PropertyGenerator

**Parameters:**

name - Property name.

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,  
                                     RenderableOp op)
```

Returns the specified property.

**Specified by:**

getProperty in interface PropertyGenerator

**Parameters:**

name - Property name.

---

## javax.media.jai.operator Class ConstantDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.ConstantDescriptor
```

---

public class **ConstantDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Constant" operation.

The Constant operation creates a multi-banded, tiled rendered image, where all the pixels from the same band have a constant value. The width and height of the image must be specified and greater than 0. At least one constant must be supplied. The number of bands of the image is determined by the number of constant pixel values supplied in the "bandValues" parameter. The data type is determined by the type of the constants; this means all elements of the bandValues array must be of the same type. If the bandValues array is a Short array, then TYPE\_USHORT is used if all values are non-negative; otherwise TYPE\_SHORT is used.

---

### getParamMinValue

public java.lang.Number **getParamMinValue**(int index)  
Returns the minimum legal value of a specified numeric parameter for this operation.  
**Overrides:**  
getParamMinValue in class OperationDescriptorImpl

---

### validateParameters

protected boolean **validateParameters**(java.awt.image.renderable.ParameterBlock args,  
java.lang.StringBuffer message)  
Validates the input parameters.  
In addition to the standard checks performed by the superclass method, this method checks that "width" and "height" are greater than 0 and that "bandValues" has length at least 1.  
**Overrides:**  
validateParameters in class OperationDescriptorImpl

---

---

## javax.media.jai.operator Class ConvolveDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.ConvolveDescriptor
```

---

public class **ConvolveDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Convolve" operation.

Convolution is a spatial operation that computes each output sample by multiplying elements of a kernel with the samples surrounding a particular source sample.

For each destination sample, the kernel is rotated 180 degrees and its "key element," or origin, is placed over the source pixel corresponding with the destination pixel. The kernel elements are multiplied with the source pixels beneath them, and the resulting products are summed together to produce the destination sample value.

Pseudocode for the convolution operation on a single sample `dst[x][y]` is as follows, assuming the kernel is of size width x height and has already been rotated through 180 degrees. The kernel's Origin element is located at position (xOrigin, yOrigin):

```
dst[x][y] = 0;
for (int i = -xOrigin; i < -xOrigin + width; i++) {
    for (int j = -yOrigin; j < -yOrigin + height; j++) {
        dst[x][y] += src[x + i][y + j]*kernel[xOrigin + i][yOrigin + j];
    }
}
```

Convolution, like any neighborhood operation, leaves a band of pixels around the edges undefined. For example, for a 3x3 kernel only four kernel elements and four source pixels contribute to the convolution pixel at the corners of the source image. Pixels that do not allow the full kernel to be applied to the source are not included in the destination image. A "Border" operation may be used to add an appropriate border to the source image in order to avoid shrinkage of the image boundaries.

The kernel may not be bigger in any dimension than the image data.

## javax.media.jai.operator Class CropDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.CropDescriptor
```

---

public class **CropDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Crop" operation.

The Crop operation takes one rendered or renderable image and crops the image to a specified rectangular area. The rectangular area must not be empty, and must be fully contained within the source image bounds.

For rendered images the supplied origin and dimensions are used to determine the smallest rectangle with integral origin and dimensions which encloses the rectangular area requested.

For renderable images the rectangular area is specified in rendering-independent coordinates. When the image is rendered this area will be mapped to rendered image coordinates using the affine transform supplied for the rendering. The crop bounds in rendered coordinates are defined to be the minimum bounding box of the rectangular area mapped to rendered image coordinates.

## javax.media.jai.operator Class DFTDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.DFTDescriptor
```

---

public class **DFTDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "DFT" operation.

The "DFT" operation computes the discrete Fourier transform of an image. A negative exponential is used as the basis function for the transform. The operation supports real-to-complex, complex-to-complex, and complex-to-real transforms. A complex image must have an even number of bands, with the even bands (0, 2, ...) representing the real parts and the odd bands (1, 3, ...) the imaginary parts of each complex pixel.

The nature of the source and destination data is specified by the "dataNature" operation parameter. If the source data are complex then the number of bands in the source image must be a multiple of 2. The number of bands in the destination must match that which would be expected given the number of bands in the source image and the specified nature of the source and destination data. If the source image is real then the number of bands in the destination will be twice that in the source. If the destination image is real then the number of bands in the destination will be half that in the source. Otherwise the number of bands in the source and destination must be equal.

If an underlying fast Fourier transform (FFT) implementation is used which requires that the image dimensions be powers of 2, then the width and height may each be increased to the power of 2 greater than or equal to the original width and height, respectively.

"DFT" defines a PropertyGenerator that sets the "COMPLEX" property of the image to `java.lang.Boolean.FALSE` if the "dataNature" operation parameter is equal to `COMPLEX_TO_REAL` and to `java.lang.Boolean.TRUE` otherwise. The value of this property may be retrieved by calling the `getProperty()` method with "COMPLEX" as the property name.

## javax.media.jai.operator Class DivideByConstDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.DivideByConstDescriptor
```

---

public class **DivideByConstDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "DivideByConst" operation.

The `DivideByConst` operation takes one rendered or renderable source image and an array of double constants, and divides every pixel of the same band of the source by the constant from the corresponding array entry. If the number of constants supplied is less than the number of bands of the destination, then the constant from entry 0 is applied to all the bands. Otherwise, a constant from a different entry is applied to each band.

In case of division by 0, if the numerator is 0, then the result is set to 0; otherwise, the result is set to the maximum value supported by the destination data type.

By default, the destination image bound, data type, and number of bands are the same as the source image. If the result of the operation underflows/overflows the minimum/maximum value supported by the destination data type, then it will be clamped to the minimum/maximum value respectively.

The destination pixel values are defined by the pseudocode:

```
if (constants.length < dstNumBands) {
    dst[x][y][b] = srcs[x][y][b]/constants[0];
} else {
    dst[x][y][b] = srcs[x][y][b]/constants[b];
}
```

## javax.media.jai.operator Class DivideComplexDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.DivideComplexDescriptor
```

---

```
public class DivideComplexDescriptor
extends OperationDescriptorImpl
```

An `OperationDescriptor` describing the "DivideComplex" operation.

The "DivideComplex" operation divides two images representing complex data. The source images must each contain an even number of bands with the even-indexed bands (0, 2, ...) representing the real and the odd-indexed bands (1, 3, ...) the imaginary parts of each pixel. The destination image similarly contains an even number of bands with the same interpretation and with contents defined by:

```
a = src0[x][y][2*k];
b = src0[x][y][2*k+1];
c = src1[x][y][2*k];
d = src1[x][y][2*k+1];
```

```
dst[x][y][2*k] = (a*c + b*d)/(c^2 + d^2)
dst[x][y][2*k+1] = (b*c - a*d)/(c^2 + d^2)
```

where  $0 \leq k < \text{numBands}/2$ . With one exception, the number of bands of the destination image is the same as the minimum of the number of bands of the two sources, and the data type is the biggest data type of the sources. The exception occurs when one of the source images has two bands, the other source image has  $N = 2 \cdot K$  bands where  $K > 1$ , and an `ImageLayout` hint is provided containing a destination `SampleModel` which specifies  $M = 2 \cdot L$  bands for the destination image where  $L > 1$  and  $L \leq K$ . In this special case if the first source has 2 bands its single complex component will be divided by each of the first  $L$  complex components of the second source; if the second source has 2 bands its single complex component will divide each of the  $L$  complex components of the first source.

If the result of the operation underflows/overflows the minimum/maximum value supported by the destination data type, then it will be clamped to the minimum/maximum value respectively.

"DivideComplex" defines a `PropertyGenerator` that sets the "COMPLEX" property of the image to

`java.lang.Boolean.TRUE`, which may be retrieved by calling the `getProperty()` method with "COMPLEX" as the property name.

### Resource List

## javax.media.jai.operator

### Class DivideDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.DivideDescriptor
```

---

public class **DivideDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Divide" operation.

The Divide operation takes two rendered or renderable images, and for every pair of pixels, one from each source image of the corresponding position and band, divides the pixel from the first source by the pixel from the second source. No additional parameters are required for this operation.

In case of division by 0, if the numerator is 0, then the result is set to 0; otherwise, the result is set to the maximum value supported by the destination data type.

The two source images may have different number of bands and data types. By default, the destination image bound is the intersection of the two source image bounds. If the two sources don't intersect, the destination will have a width and a height of 0. The default number of bands of the destination image is the same as the least number of bands of the sources, and the data type is the biggest data type of the sources.

As a special case, if one of the source images has N bands ( $N > 1$ ), the other source has 1 band, and an ImageLayout hint is provided containing a destination SampleModel with K bands ( $1 < K \leq N$ ), then the single band of the 1-banded source will be divided by or into to each of the first K bands of the N-band source.

If the result of the operation underflows/overflows the minimum/maximum value supported by the destination data type, then it will be clamped to the minimum/maximum value respectively.

The destination pixel values are defined by the pseudocode:

```
dst[x][y][dstBand] = srcs[0][x][y][src0Band]/srcs[1][x][y][src1Band];
```

### Class DivideIntoConstDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.DivideIntoConstDescriptor
```

---

public class **DivideIntoConstDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "DivideIntoConst" operation.

The `DivideIntoConst` operation takes one rendered or renderable image and an array of double constants, and divides every pixel of the same band of the source into the constant from the corresponding array entry. If the number of constants supplied is less than the number of bands of the destination, then the constant from entry 0 is applied to all the bands. Otherwise, a constant from a different entry is applied to each band.

In case of division by 0, if the numerator is 0, then the result is set to 0; otherwise, the result is set to the maximum value supported by the destination data type.

By default, the destination image bound, data type, and number of bands are the same as the source image. If the result of the operation underflows/overflows the minimum/maximum value supported by the destination data type, then it will be clamped to the minimum/maximum value respectively.

The destination pixel values are defined by the pseudocode:

```
if (constants.length < dstNumBands) {
    dst[x][y][b] = constants[0]/src[x][y][b];
} else {
    dst[x][y][b] = constants[b]/src[x][y][b];
}
```

#### Resource List

Name	Value
GlobalName	DivideIntoConst
LocalName	DivideIntoConst
Vendor	com.sun.media.jai
Description	Divides a rendered image into constants.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/DivideIntoConstDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/DivideIntoConstDescriptor.html</a>
Version	1.0
arg0Desc	The constants to be divided into.

### Field Detail

#### resources

```
private static final java.lang.String[][] resources
```

The resource strings that provide the general documentation and specify the parameter list for this operation.

---

## paramClasses

private static final java.lang.Class[] **paramClasses**

The parameter class list for this operation. The number of constants provided should be either 1, in which case this same constant is applied to all the source bands; or the same number as the source bands, in which case one constant is applied to each band.

---

## paramNames

private static final java.lang.String[] **paramNames**

The parameter name list for this operation.

---

## paramDefaults

private static final java.lang.Object[] **paramDefaults**

The parameter default value list for this operation.

## Constructor Detail

### DivideIntoConstDescriptor

public **DivideIntoConstDescriptor**()

Constructor.

## Method Detail

### isRenderableSupported

public boolean **isRenderableSupported**()

Returns true since renderable operation is supported.

**Overrides:**

isRenderableSupported in class OperationDescriptorImpl

---

### validateParameters

protected boolean **validateParameters**(java.awt.image.renderable.ParameterBlock args,  
java.lang.StringBuffer message)

Validates the input parameters.

In addition to the standard checks performed by the superclass method, this method checks that the length of the "constants" array is at least 1.

**Overrides:**

validateParameters in class OperationDescriptorImpl

---

## javax.media.jai.operator

### Class EncodeDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.EncodeDescriptor
```

---

public class **EncodeDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "Encode" operation. The "Encode" operation writes an image to a given `OutputStream` in a specified format using the supplied encoding parameters.

The third parameter contains an instance of `ImageEncodeParam` to be used during the decoding. It may be set to `null` in order to perform default encoding, or equivalently may be omitted. If non-`null`, it must be of the correct class type for the selected format.

**The classes in the `com.sun.media.jai.codec` package are not a committed part of the JAI API. Future releases of JAI will make use of new classes in their place. This class will change accordingly.**

#### Resource List

Name	Value
GlobalName	encode
LocalName	encode
Vendor	com.sun.media.jai
Description	Stores an image to an <code>OutputStream</code> .
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/EncodeDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/EncodeDescriptor.html</a>
Version	1.0
arg0Desc	The <code>OutputStream</code> to write to.
arg1Desc	The format of the created file.
arg2Desc	The encoding parameters.

#### Parameter List

Name	Class Type	Default Value
stream	<code>java.io.OutputStream</code>	<code>NO_PARAMETER_DEFAULT</code>
format	<code>java.lang.String</code>	"tiff"
param	<code>com.sun.media.jai.codec.ImageEncodeParam</code>	<code>null</code>

## javax.media.jai.operator

### Class ErrorDiffusionDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.ErrorDiffusionDescriptor
```

---

public class **ErrorDiffusionDescriptor**

extends OperationDescriptorImpl

An OperationDescriptor describing the "ErrorDiffusion" operation.

The "ErrorDiffusion" operation performs color quantization by finding the nearest color to each pixel in a supplied color map and "diffusing" the color quantization error below and to the right of the pixel.

#### Resource List

Name	Value
GlobalName	ErrorDiffusion
LocalName	ErrorDiffusion
Vendor	com.sun.media.jai
Description	Performs error diffusion color quantization using a specified color map and error filter.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/ErrorDiffusionDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/ErrorDiffusionDescriptor.html</a>
Version	1.0
arg0Desc	The color map.
arg1Desc	The error filter kernel.

#### Parameter List

Name	Class Type	Default Value
colorMap	javax.media.jai.LookupTableJAI	NO_PARAMETER_DEFAULT
errorKernel	javax.media.jai.KernelJAI	javax.media.jai.KernelJAI.ERROR_FILTER_FLOYD_STEINBERG

#### See Also:

<h2>Constructor Detail</h2>
-----------------------------

## ErrorDiffusionDescriptor

public **ErrorDiffusionDescriptor**()

Constructor.

---

## javax.media.jai.operator Class ExpDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.ExpDescriptor
```

---

public class **ExpDescriptor**

extends OperationDescriptorImpl

An OperationDescriptor describing the "Exp" operation.

The "Exp" operation takes the exponential of the pixel values of an image. The pixel values of the destination image are defined by the pseudocode:

```
dst[x][y][b] = java.lang.Math.exp(src[x][y][b])
```

For integral image datatypes, the result will be rounded and clamped as needed.

### Resource List

Name	Value
GlobalName	Exp
LocalName	Exp
Vendor	com.sun.media.jai
Description	Computes the exponential of the pixel values of an image.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/ExpDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/ExpDescriptor.html</a>
Version	1.0

No parameters are needed for the "Exp" operation.

### See Also:

## javax.media.jai.operator

### Class ExtremaDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.ExtremaDescriptor
```

---

public class **ExtremaDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "Extrema" operation.

The Extrema operation scans a specific region of a rendered image and finds the maximum and minimum pixel values for each band within that region of the image. The image data pass through this operation unchanged.

The region-wise maximum and minimum pixel values may be obtained as properties. Calling the `getProperty` method on this operation with "extrema" as the property name retrieves both the region-wise maximum and minimum pixel values. Calling it with "maximum" as the property name retrieves the region-wise maximum pixel value, and with "minimum" as the property name retrieves the region-wise minimum pixel value. The return value for "extrema" has type `double[2][#bands]`, and those for "maximum" and "minimum" have type `double[#bands]`.

The region of interest (ROI) does not have to be a rectangle. It may be `null`, in which case the entire image is scanned to find the image-wise maximum and minimum pixel values for each band.

The set of pixels scanned may be further reduced by specifying the "xPeriod" and "yPeriod" parameters that represent the sampling rate along each axis. These variables may not be less than 1. However, they may be `null`, in which case the sampling rate is set to 1; that is, every pixel in the ROI is processed.

#### Resource List

Name	Value
GlobalName	Extrema
LocalName	Extrema
Vendor	com.sun.media.jai
Description	Finds the maximum and minimum pixel value in each band of an image.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/ExtremaDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/ExtremaDescriptor.html</a>
Version	1.0
arg0Desc	The region of the image to scan.
arg1Desc	The horizontal sampling rate, may not be less than 1.
arg2Desc	The vertical sampling rate, may not be less than 1.

#### Parameter List

## javax.media.jai.operator Class FileLoadDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.FileLoadDescriptor
```

---

public class **FileLoadDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "FileLoad" operation.

The `validateArguments()` method checks that the named file exists and is readable. If not, it will return `false`, causing `JAI.createNS()` to throw an `IllegalArgumentException`.

The allowable formats are those registered with the `com.sun.media.jai.codec.ImageCodec` class.

The second parameter contains an instance of `ImageDecodeParam` to be used during the decoding. It may be set to `null` in order to perform default decoding, or equivalently may be omitted.

**The classes in the `com.sun.media.jai.codec` package are not a committed part of the JAI API. Future releases of JAI will make use of new classes in their place. This class will change accordingly.**

### Resource List

Name	Value
GlobalName	fileload
LocalName	fileload
Vendor	com.sun.media.jai
Description	Reads an image from a file.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/FileLoadDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/FileLoadDescriptor.html</a>
Version	1.0
arg0Desc	The path of the file to read from.
arg1Desc	The <code>ImageDecodeParam</code> to use.

### Parameter List

Name	Class Type	Default Value
filename	<code>java.lang.String</code>	<code>NO_PARAMETER_DEFAULT</code>
param	<code>com.sun.media.jai.codec.ImageDecodeParam</code>	<code>null</code>

## paramDefaults

```
private static final java.lang.Object[] paramDefaults
```

The parameter default values for the "FileLoad" operation.

## Constructor Detail

### FileLoadDescriptor

```
public FileLoadDescriptor()
```

Constructor.

## Method Detail

### validateParameters

```
protected boolean validateParameters(java.awt.image.renderable.ParameterBlock args,  
                                     java.lang.StringBuffer msg)
```

Validates the input parameters.

In addition to the standard checks performed by the superclass method, this method checks that the source file exists and is readable.

#### Overrides:

validateParameters in class OperationDescriptorImpl

---

## javax.media.jai.operator

### Class FileStoreDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.FileStoreDescriptor
```

---

public class **FileStoreDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "FileStore" operation. The "FileStore" operation writes an image to a given file in a specified format using the supplied encoding parameters.

The third parameter contains an instance of `ImageEncodeParam` to be used during the decoding. It may be set to `null` in order to perform default encoding, or equivalently may be omitted. If non-`null`, it must be of the correct class type for the selected format.

The requested file path must be writable.

**The classes in the `com.sun.media.jai.codec` package are not a committed part of the JAI API. Future releases of JAI will make use of new classes in their place. This class will change accordingly.**

#### Resource List

Name	Value

## javax.media.jai.operator

### Class FormatDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.FormatDescriptor
```

---

```
public class FormatDescriptor
extends OperationDescriptorImpl
```

An `OperationDescriptor` describing the "Format" operation.

The "Format" operation performs reformatting on an image. It is capable of casting the pixel values of an image to a given data type, replacing the `SampleModel` and `ColorModel` of an image, and restructuring the image's tile grid layout. The pixel values of the destination image are defined by the pseudocode:

```
dst[x][y][b] = cast(src[x][y][b], dataType)
```

where "dataType" is one of the constants `TYPE_BYTE`, `TYPE_SHORT`, `TYPE_USHORT`, `TYPE_INT`, `TYPE_FLOAT`, or `TYPE_DOUBLE` from `java.awt.image.DataBuffer`.

The output `SampleModel`, `ColorModel` and tile grid layout are specified by passing an `ImageLayout` object as a `RenderingHint` named "ImageLayout". The output image will have a `SampleModel` compatible with the one specified in the layout hint wherever possible; however, for output data types of `float` and `double` a `ComponentSampleModel` will be used regardless of the value of the hint parameter.

The `ImageLayout` may also specify a tile grid origin and size which will be respected.

The typecasting performed by the `Format` function is defined by the following set of expressions, dependent on the data types of the source and destination. Casting an image to its current data type is a no-op. See The Java Language Specification for the definition of type conversions between primitive types.

In most cases, it is not necessary to explicitly perform widening typecasts since they will be performed automatically by image operators when handed source images having different datatypes.

Source Type	Destination Type	Action
BYTE	SHORT	(short)(x & 0xff)
BYTE	USHORT	(short)(x & 0xff)
BYTE	INT	(int)(x & 0xff)
BYTE	FLOAT	(float)(x & 0xff)
BYTE	DOUBLE	(double)(x & 0xff)
SHORT	BYTE	(byte)clamp((int)x, 0, 255)
SHORT	USHORT	(short)clamp((int)x, 0, 32767)
SHORT	INT	(int)x
SHORT	FLOAT	(float)x
SHORT	DOUBLE	(double)x
USHORT	BYTE	(byte)clamp((int)x & 0xffff, 0, 255)
USHORT	SHORT	(short)clamp((int)x & 0xffff, 0, 32767)
USHORT	INT	(int)(x & 0xffff)
USHORT	FLOAT	(float)(x & 0xffff)
USHORT	DOUBLE	(double)(x & 0xffff)
INT	BYTE	(byte)clamp(x, 0, 255)
INT	SHORT	(short)clamp(x, -32768, 32767)
INT	USHORT	(short)clamp(x, 0, 65535)
INT	FLOAT	(float)x
INT	DOUBLE	(double)x
FLOAT	BYTE	(byte)clamp((int)x, 0, 255)
FLOAT	SHORT	(short)clamp((int)x, -32768, 32767)
FLOAT	USHORT	(short)clamp((int)x, 0, 65535)
FLOAT	INT	(int)x
FLOAT	DOUBLE	(double)x
DOUBLE	BYTE	(byte)clamp((int)x, 0, 255)
DOUBLE	SHORT	(short)clamp((int)x, -32768, 32767)
DOUBLE	USHORT	(short)clamp((int)x, 0, 65535)
DOUBLE	INT	(int)x
DOUBLE	FLOAT	(float)x

The `clamp` function may be defined as:

```
int clamp(int x, int low, int high) {  
    return (x < low) ? low : ((x > high) ? high : x);  
}
```

## javax.media.jai.operator Class GradientMagnitudeDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.GradientMagnitudeDescriptor
```

---

public class **GradientMagnitudeDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "GradientMagnitude" operation.

The "GradientMagnitude" operation is an edge detector which computes the magnitude of the image gradient vector in two orthogonal directions.

The result of the "GradientMagnitude" operation may be defined as:

$$\text{dst}[x][y][b] = ((\text{SH}(x,y,b))^2 + (\text{SV}(x,y,b))^2)^{0.5}$$

where  $\text{SH}(x,y,b)$  and  $\text{SV}(x,y,b)$  are the horizontal and vertical gradient images generated from band  $b$  of the source image by correlating it with the supplied orthogonal (horizontal and vertical) gradient masks. Origins set on the kernels will be ignored. The origins are assumed to be width/2 & height/2.

### Resource List

Name	Value
GlobalName	GradientMagnitude
LocalName	GradientMagnitude
Vendor	com.sun.media.jai
Description	Performs gradient magnitude edge detection on an image.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jaiapi/javax.media.jai.operator.GradientMagnitudeDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jaiapi/javax.media.jai.operator.GradientMagnitudeDescriptor.html</a>
Version	1.0
arg0Desc	A gradient mask
arg1Desc	A gradient mask orthogonal to the first one.

### Parameter List

Name	Class Type	Default Value
mask1	javax.media.jai.KernelJAI	KernalJAI.GRADIENT_MASK_SOBEL_HORIZONTAL
mask2	javax.media.jai.KernelJAI	KernalJAI.GRADIENT_MASK_SOBEL_VERTICAL

## javax.media.jai.operator

### Class HistogramDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.HistogramDescriptor
```

---

public class **HistogramDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Histogram" operation.

The Histogram operation scans a specific region of a rendered image and generates a histogram based on the pixel values within that region of the image. The histogram data is stored in the user supplied `javax.media.jai.Histogram` object, and may be retrieved by calling the `getProperty` method on this operation with "histogram" as the property name. The return value will be of type `javax.media.jai.Histogram`. The image data pass through this operation unchanged.

The region of interest (ROI) does not have to be a rectangle. It may be `null`, in which case the entire image is scanned to generate the histogram.

The set of pixels scanned may be further reduced by specifying the "xPeriod" and "yPeriod" parameters that represent the sampling rate along each axis. These variables may not be less than 1. However, they may be `null`, in which case the sampling rate is set to 1; that is, every pixel in the ROI is processed.

## javax.media.jai.operator Class IDCTDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.IDCTDescriptor
```

---

public class **IDCTDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "IDCT" operation.

The "IDCT" operation computes the inverse even discrete cosine transform (DCT) of an image. Each band of the destination image is derived by performing a two-dimensional inverse DCT on the corresponding band of the source image.

### Resource List

Name	Value
GlobalName	IDCT
LocalName	IDCT
Vendor	com.sun.media.jai
Description	Computes the inverse discrete cosine transform of an image.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/IDCTDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/IDCTDescriptor.html</a>
Version	1.0

No parameters are needed for the "IDCT" operation.

```
public boolean isRenderableSupported()
```

Returns true since renderable operation is supported.

### Overrides:

isRenderableSupported in class OperationDescriptorImpl

---

## javax.media.jai.operator Class IDFTDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.IDFTDescriptor
```

---

public class **IDFTDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "IDFT" operation.

The "IDFT" operation computes the inverse discrete Fourier transform of an image. A positive exponential is used as the basis function for the transform. The operation supports real-to-complex, complex-to-complex, and complex-to-real transforms. A complex image must have an even number of bands, with the even bands (0, 2, ...) representing the real parts and the odd bands (1, 3, ...) the imaginary parts of each complex pixel.

The nature of the source and destination data is specified by the "dataNature" operation parameter. If the source data are complex then the number of bands in the source image must be a multiple of 2. The number of bands in the destination must match that which would be expected given the number of bands in the source image and the specified nature of the source and destination data. If the source image is real then the number of bands in the destination will be twice that in the source. If the destination image is real then the number of bands in the destination will be half that in the source. Otherwise the number of bands in the source and destination must be equal.

If an underlying fast Fourier transform (FFT) implementation is used which requires that the image dimensions be powers of 2, then the width and height may each be increased to the power of 2 greater than or equal to the original width and height, respectively.

"IDFT" defines a PropertyGenerator that sets the "COMPLEX" property of the image to `java.lang.Boolean.FALSE` if the "dataNature" operation parameter is equal to `DFTDescriptor.COMPLEX_TO_REAL` and to `java.lang.Boolean.TRUE` otherwise. The value of this property may be retrieved by calling the `getProperty()` method with "COMPLEX" as the property name.

### Resource List

Name	Value
GlobalName	IDFT
LocalName	IDFT
Vendor	com.sun.media.jai
Description	Computes the discrete Fourier transform of an image.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/IDFTDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/IDFTDescriptor.html</a>
Version	1.0
arg0Desc	The type of scaling to be used.
arg1Desc	The nature of the data.

### Parameter List

Name	Class Type	Default Value
scalingType	Integer	DFTDescriptor.SCALING_DIMENSIONS
dataNature	Integer	DFTDescriptor.COMPLEX_TO_REAL

### See Also:

OperationDescriptor, DFTDescriptor

---

## Field Detail

### resources

```

```

The parameter default value list for this operation.

## Constructor Detail

### IDFTDescriptor

```
public IDFTDescriptor()
```

Constructor.

## Method Detail

### isRenderableSupported

```
public boolean isRenderableSupported()
```

Returns true since renderable operation is supported.

**Overrides:**

isRenderableSupported in class OperationDescriptorImpl

### validateArguments

```
public boolean validateArguments(java.awt.image.renderable.ParameterBlock args,  
                                java.lang.StringBuffer msg)
```

Validates the input source and parameters.

In addition to the standard checks performed by the superclass method, this method checks that "scalingType" is one of SCALING\_NONE, SCALING\_UNITARY, or SCALING\_DIMENSIONS, and that "dataNature" is one of REAL\_TO\_COMPLEX, COMPLEX\_TO\_COMPLEX, or COMPLEX\_TO\_REAL. Also, if "dataNature" is COMPLEX\_TO\_COMPLEX or COMPLEX\_TO\_REAL the number of source bands must be even.

**Overrides:**

validateArguments in class OperationDescriptorImpl

### getPropertyGenerators

```
public PropertyGenerator[] getPropertyGenerators()
```

Returns an array of PropertyGenerators implementing property inheritance for the "IDFT" operation.

**Returns:**

An array of property generators.

**Overrides:**

getPropertyGenerators in class OperationDescriptorImpl

---

## javax.media.jai.operator Class IDFTPropertyGenerator

```
java.lang.Object
|
+-- javax.media.jai.operator.IDFTPropertyGenerator
```

---

class **IDFTPropertyGenerator**

extends java.lang.Object

implements PropertyGenerator

This property generator computes the properties for the operation "IDFT" dynamically.

---

### Constructor Detail

#### IDFTPropertyGenerator

```
public IDFTPropertyGenerator()
```

Constructor.

### Method Detail

#### getPropertyNames

```
public java.lang.String[] getPropertyNames()
```

Returns the valid property names for the operation "IDFT".

**Specified by:**

getPropertyNames in interface PropertyGenerator

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,
                                   RenderedOp op)
```

Returns the specified property.

**Specified by:**

getProperty in interface PropertyGenerator

**Parameters:**

name - Property name.

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,
                                   RenderableOp op)
```

Returns the specified property.

**Specified by:**

getProperty in interface PropertyGenerator

**Parameters:**

name - Property name.

---

## javax.media.jai.operator Class IIPDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.IIPDescriptor
```

---

```
public class IIPDescriptor
    extends OperationDescriptorImpl
```

An `OperationDescriptor` describing the "IIP" operation.

This operation provides client-side support of the Internet Imaging Protocol (IIP) in both the rendered and renderable modes. It creates a `java.awt.image.RenderedImage` or a `java.awt.image.renderable.RenderableImage` based on the data received from the IIP server, and optionally applies a sequence of operations to the created image.

The operations that may be applied and the order in which they are applied are defined in section 2.2.1.1 of the Internet Imaging Protocol Specification version 1.0.5. Some or all of the requested operations may be executed on the IIP server if it is determined that the server supports such operations. Any of the requested operations not supported by the server will be executed on the host on which the operation chain is rendered.

The processing sequence for the supplied operations is as follows:

- filtering (blur or sharpen);
- tone and color correction ("color twist");
- contrast adjustment;
- selection of source rectangle of interest;
- spatial orientation (rendering-independent affine transformation);
- selection of destination rectangle of interest;
- rendering transformation (renderable mode only);
- transposition (rotation and/or mirroring).

As indicated, the rendering transformation is performed only in renderable mode processing. This transformation is derived from the `AffineTransform` supplied in the `RenderContext` when rendering actually occurs. Rendered mode processing creates a `RenderedImage` which is the default rendering of the `RenderableImage` created in renderable mode processing.

The "URL" parameter specifies the URL of the IIP image as a `java.lang.String`. It must represent a valid URL, and include any required FIF or SDS commands. It cannot be null.

The "subImages" parameter optionally indicates the sub-images to be used by the server to get the images at each resolution level. The values in this `int` array cannot be negative. If this parameter is not specified, or if the array is too short (length is 0), or if a negative value is specified, then this operation will use the zeroth sub-image of the resolution level actually processed.

The "filter" parameter specifies a blur or sharpen operation: a positive value indicates sharpen and a negative value blur. A unit step should produce a perceptible change in the image. The default value is 0 which signifies that no filtering will occur.

The "colorTwist" parameter represents a 4x4 matrix stored in row-major order and should have an array length of at least 16. If an array of length greater than 16 is specified, all elements from index 16 and beyond are ignored. Elements 12, 13 and 14 must be 0. This matrix will be applied to the (possibly padded) data in an intermediate normalized PhotoYCC color space with a premultiplied alpha channel. This operation will force an alpha channel to be added to the image if the last column of the last row of the color twist matrix is not 1.0F. Also, if the image originally has a grayscale color space it will be cast up to RGB if casting the data back to grayscale after applying the color twist matrix would result in any loss of data.

The "contrast" parameter specifies a contrast enhancement operation with increasing contrast for larger value. It must be greater than or equal to 1.0F. A value of 1.0F indicates no contrast adjustment.

The "sourceROI" parameter specifies the rectangle of interest in the source image in rendering-independent coordinates. The intersection of this rectangle with the rendering-independent bounds of the source image must equal itself. The rendering-independent bounds of the source image are defined to be (0.0F, 0.0F, *r*, 1.0F) where *r* is the aspect ratio (width/height) of the source image. Note that the source image will not in fact be cropped to these limits but values outside of this rectangle will be suppressed.

The "transform" parameter represents an affine backward mapping to be applied in rendering-independent coordinates. Note that the direction of transformation is opposite to that of the `AffineTransform` supplied in the `RenderContext` which is a forward mapping. The default value of this transform is the identity mapping. The supplied `AffineTransform` must be invertible.

The "aspectRatio" parameter specifies the rendering-independent width of the destination image and must be positive. The rendering-independent bounds of the destination image are (0.0F, 0.0F, aspectRatio, 1.0F). If this parameter is not provided the destination aspect ratio defaults to that of the source.

The "destROI" parameter specifies the rectangle of interest in the destination image in rendering-independent coordinates. This rectangle must have a non-empty intersection with the rendering-independent bounds of the destination image but is not constrained to the destination image bounds.

A counterclockwise rotation may be applied to the destination image. However, the angle is limited to 0, 90, 180, or 270 degrees. By default, the destination image is not rotated.

The "mirrorAxis" parameter may be null, in which case no flipping is applied, or a String of "x", "X", "y", or "Y".

The "ICCProfile" parameter may only be used with client-side processing or with server-side processing if the connection protocol supports the ability to transfer a profile.

The "JPEGQuality" and "JPEGTable" parameters are only used with server-side processing. If provided, JPEGQuality must be in the range [0,100] and JPEGTable in [1,255].

There is no source image associated with this operation.

#### Resource List

## Field Detail

**resources**

```
private static final java.lang.String[][] resources
```

The resource strings that provide the general documentation and specify the parameter list for this operation.

---

**paramClasses**

```
private static final java.lang.Class[] paramClasses
```

The parameter class types for this operation.

---

**paramNames**

```
private static final java.lang.String[] paramNames
```

The parameter names for this operation.

---

**paramDefaults**

```
private static final java.lang.Object[] paramDefaults
```

The parameter default values for this operation. For those parameters whose default value is null, an appropriate value is chosen by the individual implementation.

## Constructor Detail

### IIPDescriptor

```
public IIPDescriptor()  
    Constructor.
```

## Method Detail

### isRenderableSupported

```
public boolean isRenderableSupported()  
    Overrides super class's default implementation to return true because this operation supports renderable mode.  
Overrides:  
    isRenderableSupported in class OperationDescriptorImpl
```

---

### getParamMinValue

```
public java.lang.Number getParamMinValue(int index)  
    Returns the minimum legal value of a specified numeric parameter for this operation. If the supplied index does not correspond to a numeric parameter, this method returns null.  
Throws:  
    ArrayIndexOutOfBoundsException - if index is less than 0 or greater than 13.  
Overrides:  
    getParamMinValue in class OperationDescriptorImpl
```

---

### getParamMaxValue

```
public java.lang.Number getParamMaxValue(int index)  
    Returns the maximum legal value of a specified numeric parameter for this operation. If the supplied index does not correspond to a numeric parameter, this method returns null.  
Throws:  
    ArrayIndexOutOfBoundsException - if index is less than 0 or greater than 13.  
Overrides:  
    getParamMaxValue in class OperationDescriptorImpl
```

---

### validateParameters

```
protected boolean validateParameters(java.awt.image.renderable.ParameterBlock args,  
                                     java.lang.StringBuffer msg)
```

Validates the input parameters.

In addition to the standard checks performed by the superclass method, this method checks that:

- the supplied URL string specifies a valid protocol;
- the color twist, if not null, has an array length of at least 16 (all elements from index 16 and beyond are ignored and elements 12, 13, and 14 are set to 0);
- both the source and dest ROI, if not null, has a width and height greater than 0;
- the mirror axis, if not null, has a String of "x", "X", "y", or "Y";
- the destination rotation is one of the valid degrees (0, 90, 180, 270).

**Overrides:**  
 validateParameters in class OperationDescriptorImpl

---

## javax.media.jai.operator

### Class IIPResolutionDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.IIPResolutionDescriptor
```

---

public class **IIPResolutionDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "IIPResolution" operation.

This operation provides client-side support of the Internet Imaging Protocol (IIP) in the rendered mode. It is resolution-specific. It requests from the IIP server an image at a particular resolution level, and creates a `java.awt.image.RenderedImage` based on the data received from the server. Once the `RenderedImage` is created, the resolution level cannot be changed.

The layout of the created `RenderedImage` is set as follows:

- `minX`, `minY`, `tileGridXOffset`, and `tileGridYOffset` are set to 0;
- `width` and `height` are determined based on the specified resolution level;
- `tileWidth` and `tileHeight` are set to 64;
- `sampleModel` is of the type `java.awt.image.PixelInterleavedSampleModel` with byte data type and the appropriate number of bands;
- `colorModel` is of the type `java.awt.image.ComponentColorModel`, with the `ColorSpace` set to sRGB, PhotoYCC, or Grayscale, depending on the color space of the remote image; if an alpha channel is present, it will be premultiplied.

The "URL" parameter specifies the URL of the IIP image as a `java.lang.String`. It must represent a valid URL, and include any required FIF or SDS commands. It cannot be null.

The "resolution" parameter specifies the resolution level of the requested IIP image from the server. The lowest resolution level is 0, with larger integers representing higher resolution levels. If the requested resolution level does not exist, the nearest resolution level is used. If this parameter is not specified, it is set to the default value

`IIPResolutionDescriptor.MAX_RESOLUTION` which indicates the highest resolution level.

The "subImage" parameter indicates the sub-image to be used by the server to get the image at the specified resolution level. This parameter cannot be negative. If this parameter is not specified, it is set to the default value 0.

There is no source image associated with this operation.

If available from the IIP server certain properties may be set on the `RenderedImage`. The names of properties and the class types of their associated values are listed in the following table.

Property List

Property Name	Property Value Class Type
affine-transform	java.awt.geom.AffineTransform
app-name	java.lang.String

Constructor.

### Method Detail

## getParamMinValue

public java.lang.Number **getParamMinValue**(int index)  
Returns the minimum legal value of a specified numeric parameter for this operation. If the supplied index does not correspond to a numeric parameter, this method returns null.  
**Returns:**  
An Integer of value 0 if index is 1 or 2, or null if index is 0.  
**Throws:**  
ArrayIndexOutOfBoundsException - if index is less than 0 or greater than 2.  
**Overrides:**  
getParamMinValue in class OperationDescriptorImpl

## validateParameters

protected boolean **validateParameters**(java.awt.image.renderable.ParameterBlock args,  
java.lang.StringBuffer msg)  
Validates the input parameters.  
In addition to the standard checks performed by the superclass method, this method checks that the supplied URL string specifies a valid protocol.  
**Overrides:**  
validateParameters in class OperationDescriptorImpl

---

## javax.media.jai.operator Class ImageFunctionDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.ImageFunctionDescriptor
```

---

public class **ImageFunctionDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "ImageFunction" operation.

The "ImageFunction" operation generates an image on the basis of a functional description provided by an object which is an instance of a class which implements the ImageFunction interface. The (x,y) coordinates passed to the `getElements()` methods of the ImageFunction object are derived by applying an optional translation and scaling to the X- and Y-coordinates of the image. The image X- and Y-coordinates as usual depend on the values of the minimum X- and Y- coordinates of the image which need not be zero. Specifically, the function coordinates passed to `getElements()` are calculated from the image coordinates as:

```
functionX = xScale*(imageX - xTrans);
functionY = yScale*(imageY - yTrans);
```

This implies that the pixel at coordinates (*xTrans*,*yTrans*) will be assigned the value of the function at (0,0).

The number of bands in the destination image must be equal to the value returned by the `getNumElements()` method of the ImageFunction unless the `isComplex()` method of the ImageFunction returns true in which case it will be twice that. The data type of the destination image is determined by the SampleModel specified by an ImageLayout object provided via a hint. If no layout hint is provided, the data type will default to single-precision floating point. The double precision floating point form of the `getElements()` method of the ImageFunction will be invoked if and only if the data type is specified to be double. For all other data types the single precision form of `getElements()` will be invoked and the destination sample values will be clamped to the data type of the image.

The width and height of the image are provided explicitly as parameters. These values override the width and height specified via an ImageLayout if such is provided.

"ImageFunction" defines a PropertyGenerator that sets the "COMPLEX" property of the image to `java.lang.Boolean.TRUE` or `java.lang.Boolean.FALSE` depending on whether the `isComplex()` method of the ImageFunction parameter returns true or false, respectively. This property may be retrieved by calling the `getProperty()` method with "COMPLEX" as the property name.

### Resource List

## javax.media.jai.operator

### Class InvertDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.InvertDescriptor
```

---

public class **InvertDescriptor**

extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "Invert" operation.

The "Invert" operation inverts the pixel values of an image. For source images with signed data types, the pixel values of the destination image are defined by the pseudocode:

```
dst[x][y][b] = -src[x][y][b]
```

For unsigned data types, the destination values are defined by:

```
dst[x][y][b] = MAX_VALUE - src[x][y][b]
```

where `MAX_VALUE` is the maximum value supported by the system of the data type of the source pixel.

#### Resource List

Name	Value
GlobalName	Invert
LocalName	Invert
Vendor	com.sun.media.jai
Description	Invert the pixel values of an image.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/InvertDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/InvertDescriptor.html</a>
Version	1.0

No parameters are needed for the "Invert" operation.

## javax.media.jai.operator Class LogDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.LogDescriptor
```

---

### public class **LogDescriptor**

extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "Log" operation.

The "Log" operation takes the natural logarithm of the pixel values of an image. The operation is done on a per-pixel, per-band basis. For integral data types, the result will be rounded and clamped as needed. The pixel values of the destination image are defined as:

```
dst[x][y][b] = java.lang.Math.log(src[x][y][b])
```

For all integral data types, the log of 0 is set to 0. For signed integral data types (short and int), the log of a negative pixel value is set to -1.

For all floating point data types (float and double), the log of 0 is set to `-Infinity`, and the log of a negative pixel value is set to `NaN`.

#### Resource List

Name	Value
GlobalName	Log
LocalName	Log
Vendor	com.sun.media.jai
Description	Computes the natural logarithm of the pixel values of an image.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/LogDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/LogDescriptor.html</a>
Version	1.0

No parameters are needed for the "Log" operation.

## javax.media.jai.operator Class LookupDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.LookupDescriptor
```

---

public class **LookupDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Lookup" operation.

The Lookup operation takes a rendered or renderable image and a lookup table, and performs general table lookup by passing the source image through the table.

The source may be a single- or multi-banded image of data types byte, ushort, short, or int. The lookup table may be single- or multi-banded and of any JAI supported data types. The destination image must have the same data type as the lookup table, and its number of bands is determined based on the number of bands of the source and the table. If the source is single-banded, the destination has the same number of bands as the lookup table; otherwise, the destination has the same number of bands as the source.

If either the source or the table is single-banded and the other one is multi-banded, then the single band is applied to every band of the multi-banded object. If both are multi-banded, then their corresponding bands are matched up.

The table may have a set of offset values, one for each band. This value is subtracted from the source pixel values before indexing into the table data array.

It is the user's responsibility to make certain the lookup table supplied is suitable for the source image. Specifically, the table data covers the entire range of the source data. Otherwise, the result of this operation is undefined.

By the nature of this operation, the destination may have a different number of bands and/or data type from the source. The SampleModel of the destination is created in accordance with the actual lookup table used in a specific case.

The destination pixel values are defined by the pseudocode:

- If the source image is single-banded and the lookup table is single- or multi-banded, then the destination image has the same number of bands as the lookup table:  
`dst[x][y][b] = table[b][src[x][y][0] - offsets[b]]`
- If the source image is multi-banded and the lookup table is single-banded, then the destination image has the same number of bands as the source image:  
`dst[x][y][b] = table[0][src[x][y][b] - offsets[0]]`
- If the source image is multi-banded and the lookup table is multi-banded, with the same number of bands as the source image, then the destination image will have the same number of bands as the source image:  
`dst[x][y][b] = table[b][src[x][y][b] - offsets[b]]`

### Resource List

## Constructor Detail

**LookupDescriptor**

```
public LookupDescriptor()
```

Constructor.

---

## Method Detail

**isRenderableSupported**

```
public boolean isRenderableSupported()
```

Returns true since renderable operation is supported.

**Overrides:**

isRenderableSupported in class OperationDescriptorImpl

---

**validateSources**

```
protected boolean validateSources(java.awt.image.renderable.ParameterBlock args,  
                                     java.lang.StringBuffer msg)
```

Validates the input source.

In addition to the standard checks performed by the superclass method, this method checks that the source image is of integral data type.

**Overrides:**

validateSources in class OperationDescriptorImpl

---

## javax.media.jai.operator Class MagnitudeDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.MagnitudeDescriptor
```

---

public class **MagnitudeDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Magnitude" operation.

The "Magnitude" operation computes the magnitude of each pixel of a complex image. The source image must have an even number of bands, with the even bands (0, 2, ...) representing the real parts and the odd bands (1, 3, ...) the imaginary parts of each complex pixel. The destination image has at most half the number of bands of the source image with each sample in a pixel representing the magnitude of the corresponding complex source sample. The magnitude values of the destination image are defined for a given sample by the pseudocode:

```
dstPixel[x][y][b] = sqrt(src[x][y][2*b]^2 + src[x][y][2*b + 1]^2)
```

where the number of bands *b* varies from zero to one less than the number of bands in the destination image.

For integral image datatypes, the result will be rounded and clamped as needed.

"Magnitude" defines a PropertyGenerator that sets the "COMPLEX" property of the image to `java.lang.Boolean.FALSE`, which may be retrieved by calling the `getProperty()` method with "COMPLEX" as the property name.

### Resource List

Name	Value
GlobalName	Magnitude
LocalName	Magnitude
Vendor	com.sun.media.jai

## javax.media.jai.operator Class MagnitudeSquaredDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.MagnitudeSquaredDescriptor
```

---

public class **MagnitudeSquaredDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "MagnitudeSquared" operation.

The "MagnitudeSquared" operation computes the squared magnitude of each pixel of a complex image. The source image must have an even number of bands, with the even bands (0, 2, ...) representing the real parts and the odd bands (1, 3, ...) the imaginary parts of each complex pixel. The destination image has at most half the number of bands of the source image with each sample in a pixel representing the magnitude of the corresponding complex source sample. The magnitude squared values of the destination image are defined for a given sample by the pseudocode:

```
dstPixel[x][y][b] = src[x][y][2*b]^2 + src[x][y][2*b + 1]^2
```

where the number of bands *b* varies from zero to one less than the number of bands in the destination image.

For integral image datatypes, the result will be rounded and clamped as needed.

"MagnitudeSquared" defines a `PropertyGenerator` that sets the "COMPLEX" property of the image to

`java.lang.Boolean.FALSE`, which may be retrieved by calling the `getProperty()` method with "COMPLEX" as the property name.

## javax.media.jai.operator

### Class MatchCDFDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.MatchCDFDescriptor
```

---

public class **MatchCDFDescriptor**

extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "MatchCDF" operation.

The "MatchCDF" operation performs a piecewise linear mapping of the pixel values of an image such that the Cumulative Distribution Function (CDF) of the destination image matches as closely as possible a specified Cumulative Distribution Function. The desired CDF is described by an array of the form

```
float CDF[numBands][numBins[b]]
```

where

```
numBins[b]
```

denotes the number of bins in the histogram of the source image for band *b*. Each element in the array

```
CDF[b]
```

must be non-negative, the array must represent a non- decreasing sequence, and the last element of the array must be 1.0F. The source image must have a `Histogram` object available via its `getProperty()` method.

#### Resource List

Name	Value

extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "Max" operation.

The Max operation takes two rendered images, and for every pair of pixels, one from each source image of the corresponding position and band, finds the maximum pixel value. No additional parameters are required.

The two sources may have different number of bands and/or data types. By default, the destination image bound is the intersection of the two source image bounds. If the two sources don't intersect, the destination will have a width and a height of 0. The number of bands of the destination image is the same as the least number of bands of the sources, and the data type is the biggest data type of the sources.

The destination pixel values are defined by the pseudocode:

```
if (srcs[0][x][y][b] > srcs[1][x][y][b]) {
    dst[x][y][b] = srcs[0][x][y][b];
} else {
    dst[x][y][b] = srcs[1][x][y][b];
}
```

|   |
|   +-- javax.media.jai.operator.MeanDescriptor
```

---

public class **MeanDescriptor**

extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "Mean" operation.

The Mean operation scans a specific region of a rendered image and computes the mean pixel value for each band within that region of the image. The image data pass through this operation unchanged.

The region-wise mean pixel value for each band may be retrieved by calling the `getProperty` method on this operation with "mean" as the property name. The return value has type `double[ #bands ]`.

The region of interest (ROI) does not have to be a rectangle. It may be `null`, in which case the entire image is scanned to find the image-wise mean pixel value for each band.

The set of pixels scanned may be further reduced by specifying the "xPeriod" and "yPeriod" parameters that represent the sampling rate along each axis. These variables may not be less than 1. However, they may be `null`, in which case the sampling rate is set to 1; that is, every pixel in the ROI is processed.

### Class MedianFilterDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.MedianFilterDescriptor
```

---

public class **MedianFilterDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "MedianFilter" operation.

The "MedianFilter" operation is a non-linear filter which is useful for removing isolated lines or pixels while preserving the overall appearance of an image. The filter is implemented by moving a mask over the image. For each position of the mask, the center pixel is replaced by the median of the pixel values covered by the mask.

There are several shapes possible for the mask. The MedianFilter operation supports three shapes, as follows:

Square Mask:

```
x x x
x x x
x x x
```

Plus Mask:

```
  x
x x x
  x
```

X Mask:

```
x  x
  x
x  x
```

The Median operation may also be used to compute the "separable median" of a 3x3 or 5x5 region of pixels. The separable median is defined as the median of the medians of each row. For example, if the pixel values in a 3x3 window are equal to:

```
[ 1 2 3 ]
[ 5 6 7 ]
[ 4 8 9 ]
```

then the overall (non-separable) median value is 5, while the separable median is equal to the median of the three row medians: median(1, 2, 3) = 2, median(5, 6, 7) = 6, and median(4, 8, 9) = 8, yielding an overall median of 6. The separable median may be obtained by specifying a mask of type MEDIAN\_MASK\_SQUARE\_SEPARABLE.

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.MinDescriptor
```

---

public class **MinDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Min" operation.

The Min operation takes two rendered images, and for every pair of pixels, one from each source image of the corresponding position and band, finds the minimum pixel value. No additional parameters are required.

The two sources may have different number of bands and/or data types. By default, the destination image bound is the intersection of the two source image bounds. If the two sources don't intersect, the destination will have a width and a height of 0. The number of bands of the destination image is the same as the least number of bands of the sources, and the data type is the biggest data type of the sources.

The destination pixel values are defined by the pseudocode:

```
if (srcs[0][x][y][b] < srcs[1][x][y][b]) {
    dst[x][y][b] = srcs[0][x][y][b];
} else {
    dst[x][y][b] = srcs[1][x][y][b];
}
```

## javax.media.jai.operator Class MultiplyComplexDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.MultiplyComplexDescriptor
```

---

public class **MultiplyComplexDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "MultiplyComplex" operation.

The "MultiplyComplex" operation multiplies two images representing complex data. The source images must each contain an even number of bands with the even-indexed bands (0, 2, ...) representing the real and the odd-indexed bands (1, 3, ...) the imaginary parts of each pixel. The destination image similarly contains an even number of bands with the same interpretation and with contents defined by:

```
a = src0[x][y][2*k];
b = src0[x][y][2*k+1];
c = src1[x][y][2*k];
d = src1[x][y][2*k+1];

dst[x][y][2*k]   = a*c - b*d;
dst[x][y][2*k+1] = a*d + b*c;
```

where  $0 \leq k < \text{numBands}/2$ . With one exception, the number of bands of the destination image is the same as the minimum of the number of bands of the two sources, and the data type is the biggest data type of the sources. The exception occurs when one of the source images has two bands, the other source image has  $N = 2 * K$  bands where  $K > 1$ , and an ImageLayout hint is provided containing a destination SampleModel which specifies  $M = 2 * L$  bands for the destination image where  $L > 1$  and  $L \leq K$ . In this special case each of the first  $L$  complex components in the  $N$ -band source will be multiplied by the single complex component in the 1-band source.

If the result of the operation underflows/overflows the minimum/maximum value supported by the destination data type, then it will be clamped to the minimum/maximum value respectively.

"MultiplyComplex" defines a PropertyGenerator that sets the "COMPLEX" property of the image to

java.lang.Boolean.TRUE, which may be retrieved by calling the getProperty() method with "COMPLEX" as the property name.

### Resource List

## javax.media.jai.operator

### Class MultiplyConstDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.MultiplyConstDescriptor
```

---

public class **MultiplyConstDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "MultiplyConst" operation.

The `MultiplyConst` operation takes one rendered or renderable image and an array of double constants, and multiplies every pixel of the same band of the source by the constant from the corresponding array entry. If the number of constants supplied is less than the number of bands of the destination, then the constant from entry 0 is applied to all the bands. Otherwise, a constant from a different entry is applied to each band.

By default, the destination image bound, data type, and number of bands are the same as the source image. If the result of the operation underflows/overflows the minimum/maximum value supported by the destination data type, then it will be clamped to the minimum/maximum value respectively.

The destination pixel values are calculated as:

```
if (constants.length < dstNumBands) {
    dst[x][y][b] = srcs[x][y][b]*constants[0];
} else {
    dst[x][y][b] = srcs[x][y][b]*constants[b];
}
```

---

### validateParameters

protected boolean **validateParameters**(java.awt.image.renderable.ParameterBlock args,  
java.lang.StringBuffer message)

Validates the input parameter.

In addition to the standard checks performed by the superclass method, this method checks that the length of the "constants" array is at least 1.

**Overrides:**

validateParameters in class OperationDescriptorImpl

---

## javax.media.jai.operator Class MultiplyDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.MultiplyDescriptor
```

---

```
public class MultiplyDescriptor
    extends OperationDescriptorImpl
```

An `OperationDescriptor` describing the "Multiply" operation.

The Multiply operation takes two rendered or renderable source images, and multiplies every pair of pixels, one from each source image of the corresponding position and band. No additional parameters are required.

The two source images may have different numbers of bands and data types. By default, the destination image bounds are the intersection of the two source image bounds. If the sources don't intersect, the destination will have a width and height of 0.

The default number of bands of the destination image is equal to the smallest number of bands of the sources, and the data type is the smallest data type with sufficient range to cover the range of both source data types (not necessarily the range of their sums).

As a special case, if one of the source images has N bands ( $N > 1$ ), the other source has 1 band, and an `ImageLayout` hint is provided containing a destination `SampleModel` with K bands ( $1 < K \leq N$ ), then the single band of the 1-banded source is added to each of the first K bands of the N-band source.

If the result of the operation underflows/overflows the minimum/maximum value supported by the destination data type, then it will be clamped to the minimum/maximum value respectively.

The destination pixel values are defined by the pseudocode:

```
dst[x][y][dstBand] = clamp(srcs[0][x][y][src0Band] *
                           srcs[1][x][y][src1Band]);
```

## Class OrDescriptor

public class **OrDescriptor**  
extends `OperationDescriptorImpl`  
An `OperationDescriptor` describing the "Or" operation.  
The Or operation takes two rendered or renderable images, and performs bit-wise logical "or" on every pair of pixels, one from each source image of the corresponding position and band. No additional parameters are required.  
Both source images must have integral data types. The two data types may be different.  
Unless altered by an `ImageLayout` hint, the destination image bound is the intersection of the two source image bounds. If the two sources don't intersect, the destination will have a width and height of 0. The number of bands of the destination image is equal to the lesser number of bands of the sources, and the data type is the smallest data type with sufficient range to cover the range of both source data types.  
The following matrix defines the logical "or" operation.

Logical "or"

src1	src2	Result
0	0	0
0	1	1
1	0	1
1	1	1

The destination pixel values are defined by the pseudocode:  
`dst[x][y][b] = srcs[0][x][y][b] | srcs[1][x][y][b];`

Resource List

Name	Value
GlobalName	Or
LocalName	Or
Vendor	com.sun.media.jai
Description	Logically "ors" two rendered images.

### Field Detail

## resources

```
private static final java.lang.String[][] resources
```

The resource strings that provide the general documentation and specify the parameter list for this operation.

## Constructor Detail

### OrDescriptor

```
public OrDescriptor()
```

Constructor.

## Method Detail

### isRenderableSupported

```
public boolean isRenderableSupported()
```

Returns true since renderable operation is supported.

**Overrides:**

isRenderableSupported in class OperationDescriptorImpl

---

### validateSources

```
protected boolean validateSources(java.awt.image.renderable.ParameterBlock args,  
                                   java.lang.StringBuffer msg)
```

Validates the input sources.

In addition to the standard checks performed by the superclass method, this method checks that the source images are of integral data type.

**Overrides:**

validateSources in class OperationDescriptorImpl

---

## javax.media.jai.operator Class OrderedDitherDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.OrderedDitherDescriptor
```

---

public class **OrderedDitherDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "OrderedDither" operation.

The "OrderedDither" operation performs color quantization by finding the nearest color to each pixel in a supplied color cube and "shifting" the resulting index value by a pseudo-random amount determined by the values of a supplied dither mask.

The dither mask is supplied as an array of KernelJAI objects the length of which must equal the number of bands in the image. Each element of the array is a KernelJAI object which represents the dither mask matrix for the corresponding band. All KernelJAI objects in the array must have the same dimensions and contain floating point values greater than or equal to 0.0 and less than or equal to 1.0.

For all integral data types, the source image samples are presumed to occupy the full range of the respective types. For floating point data types it is assumed that the data samples have been scaled to the range [0.0, 1.0].

### Resource List

Name	Value
GlobalName	OrderedDither
LocalName	OrderedDither
Vendor	com.sun.media.jai
Description	Performs ordered dither color quantization using a specified color cube and dither mask.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/OrderedDitherDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/OrderedDitherDescriptor.html</a>
Version	1.0
arg0Desc	The color cube.
arg1Desc	The dither mask.

### Parameter List

Name	Class Type	Default Value
colorMap	javax.media.jai.ColorCube	ColorCube.BYTE_496
ditherMask	javax.media.jai.KernelJAI[]	KernelJAI.DITHER_MASK_443

### See Also:

KernelJAI, ColorCube, OperationDescriptor

## Field Detail

### resources

```
private static final java.lang.String[][] resources
```

The resource strings that provide the general documentation and specify the parameter list for this operation.

---

## paramNames

```
private static final java.lang.String[] paramNames
```

The parameter names for the "OrderedDither" operation.

---

## paramClasses

```
private static final java.lang.Class[] paramClasses
```

The parameter class types for the "OrderedDither" operation.

---

## paramDefaults

```
private static final java.lang.Object[] paramDefaults
```

The parameter default values for the "OrderedDither" operation.

## Constructor Detail

### OrderedDitherDescriptor

```
public OrderedDitherDescriptor()
```

Constructor.

## Method Detail

### isValidColorMap

```
private static boolean isValidColorMap(java.awt.image.RenderedImage sourceImage,  
                                       ColorCube colorMap,  
                                       java.lang.StringBuffer msg)
```

Method to check the validity of the color map parameter. The supplied color cube must have the same data type and number of bands as the source image.

**Parameters:**

sourceImage - The source image of the operation.  
colorMap - The color cube.  
msg - The buffer to which messages should be appended.

**Returns:**

Whether the color map is valid.

---

### isValidDitherMask

```
private static boolean isValidDitherMask(java.awt.image.RenderedImage sourceImage,  
                                         KernelJAI[] ditherMask,  
                                         java.lang.StringBuffer msg)
```

Method to check the validity of the dither mask parameter. The dither mask is an array of KernelJAI objects wherein the number of elements in the array must equal the number of bands in the source image. Furthermore all kernels in the array must have the same width and height. Finally all data elements of all kernels must be greater than or equal to zero and less than or equal to unity.

**Parameters:**

sourceImage - The source image of the operation.  
ditherMask - The dither mask.  
msg - The buffer to which messages should be appended.

**Returns:**

Whether the dither mask is valid.

---

### validateArguments

```
public boolean validateArguments(java.awt.image.renderable.ParameterBlock args,  
                                java.lang.StringBuffer msg)
```

Validates the input source and parameters.

In addition to the standard checks performed by the superclass method, this method checks that "colorMap" and "ditherMask" are valid for the given source image.

**Overrides:**

validateArguments in class OperationDescriptorImpl

---

## javax.media.jai.operator Class OverlayDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.OverlayDescriptor
```

---

public class **OverlayDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Overlay" operation.

The Overlay operation takes two rendered or renderable source images, and overlays the second source image on top of the first source image. No additional parameters are required.

The two source images must have the same data type and number of bands. However, their SampleModel types may differ. The destination image will always have the same bounding rectangle as the first source image, that is, the image on the bottom, and the same data type and number of bands as the two sources. In case the two sources don't intersect, the destination will be the same as the first source.

The destination pixel values are defined by the pseudocode:

```
if (srcs[1] contains the point (x, y)) {
    dst[x][y][b] = srcs[1][x][y][b];
} else {
    dst[x][y][b] = srcs[0][x][y][b];
}
```

### Resource List

Name	Value
GlobalName	Overlay
LocalName	Overlay
Vendor	com.sun.media.jai
Description	Overlays one rendered image on top of another.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/OverlayDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/OverlayDescriptor.html</a>
Version	1.0

### OverlayDescriptor

```
public OverlayDescriptor()  
    Constructor.
```

## Method Detail

## **isRenderableSupported**

public boolean **isRenderableSupported**()

Returns true since renderable operation is supported.

### **Overrides:**

isRenderableSupported in class OperationDescriptorImpl

---

## **validateSources**

protected boolean **validateSources**(java.awt.image.renderable.ParameterBlock args,  
java.lang.StringBuffer msg)

Validates the input sources.

In addition to the standard checks performed by the superclass method, this method checks that the source image SampleModels have the same number of bands and transfer types.

### **Overrides:**

validateSources in class OperationDescriptorImpl

---

## javax.media.jai.operator Class PNGDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.PNGDescriptor
```

---

public class **PNGDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "PNG" operation.

The "PNG" operation reads a standard PNG version 1.1 input stream. The PNG (Portable Network Graphics) specification may be found at <http://www.cdrom.com/pub/png/spec>.

The "PNG" operation implements the entire PNG specification, but provides access only to the final, high-resolution version of interlaced images.

The second parameter contains an instance of PNGDecodeParam to be used during the decoding. It may be set to null in order to perform default decoding, or equivalently may be omitted.

The documentation for PNGDecodeParam describes the possible output formats of PNG images after decoding.

**The classes in the com.sun.media.jai.codec package are not a committed part of the JAI API. Future releases of JAI will make use of new classes in their place. This class will change accordingly.**

### Resource List

Name	Value
GlobalName	PNG
LocalName	PNG
Vendor	com.sun.media.jai
Description	Reads an image from a PNG stream.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/PNGDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/PNGDescriptor.html</a>
Version	1.0
arg0Desc	The SeekableStream to read from.
arg1Desc	The PNGDecodeParam to use.

### Parameter List

Name	Class Type	Default Value
stream	com.sun.media.jai.codec.SeekableStream	NO_PARAMETER_DEFAULT
param	com.sun.media.jai.codec.PNGDecodeParam	null

## Properties

Property Name	Class	Comment
file_type	String	"PNG v. 1.0"
background_color	java.awt.Color	The suggested background color.
significant_bits	int[]	The number of significant bits stored in the file.
bit_depth	Integer	The bit depth of the file
color_type	String	One of "Grayscale", "Truecolor", "Index", "Grayscale with alpha" or "Truecolor with alpha"
interlace_method	String	"None" or "Adam7"
white_point_x	Float	The CIE X coordinate of the white point, if known.
white_point_y	Float	The CIE Y coordinate of the white point, if known.
red_x	Float	The CIE X coordinate of the red primary, if known.
red_y	Float	The CIE Y coordinate of the red primary, if known.
green_x	Float	The CIE X coordinate of the green primary, if known.
green_y	Float	The CIE Y coordinate of the green primary, if known.
blue_x	Float	The CIE X coordinate of the blue primary, if known.
blue_y	Float	The CIE Y coordinate of the blue primary, if known.
gamma	Float	The image gamma, if known.
x_pixels_per_unit	Integer	The number of horizontal pixels per unit.
y_pixels_per_unit	Integer	The number of vertical pixels per unit.
pixel_aspect_ratio	Float	The width of a pixel divided by its height.
pixel_units	String	"Meters" or null
timestamp	java.util.Date	The creation or modification time of the image.
text:*	String	The value of a tEXt chunk.
ztext:*	String	The value of a zTXt chunk (not yet implemented).
chunk:*	byte[]	The contents of any non-standard chunks.

## javax.media.jai.operator Class PNMDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.PNMDescriptor
```

---

public class **PNMDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "PNM" operation.

The "PNM" operation reads a standard PNM file, including PBM, PGM, and PPM images of both ASCII and raw formats. It stores the image data into an appropriate SampleModel.

**The classes in the `com.sun.media.jai.codec` package are not a committed part of the JAI API. Future releases of JAI will make use of new classes in their place. This class will change accordingly.**

### Resource List

Name	Value

## javax.media.jai.operator Class PatternDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.PatternDescriptor
```

---

public class **PatternDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Pattern" operation.

The "Pattern" operation defines a tiled image consisting of a repeated pattern. The width and height of the destination image must be specified. The tileWidth and tileHeight are equal to pattern's width and height. Each tile of the destination image will be defined by a reference to a shared instance of the pattern.

### Resource List

Name	Value
GlobalName	pattern
LocalName	pattern
Vendor	com.sun.media.jai
Description	Defines an image with a repeated pattern.

## javax.media.jai.operator

### Class PeriodicShiftDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.PeriodicShiftDescriptor
```

---

public class **PeriodicShiftDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "PeriodicShift" operation.

The destination image of the "PeriodicShift" operation is the infinite periodic extension of the source image with horizontal and vertical periods equal to the image width and height, respectively, shifted by a specified amount along each axis and clipped to the bounds of the source image. Thus for each band *b* the destination image sample at location (*x*,*y*) is defined by:

```
if(x < width - shiftX) {
    if(y < height - shiftY) {
        dst[x][y][b] = src[x + shiftX][y + shiftY][b];
    } else {
        dst[x][y][b] = src[x + shiftX][y - height + shiftY][b];
    }
} else {
    if(y < height - shiftY) {
        dst[x][y][b] = src[x - width + shiftX][y + shiftY][b];
    } else {
        dst[x][y][b] = src[x - width + shiftX][y - height + shiftY][b];
    }
}
```

where *shiftX* and *shiftY* denote the translation factors along the *X* and *Y* axes, respectively.

Resource List

## Constructor Detail

### PeriodicShiftDescriptor

```
public PeriodicShiftDescriptor()
```

Constructor.

## Method Detail

### isRenderableSupported

```
public boolean isRenderableSupported()
```

Returns true since renderable operation is supported.

#### Overrides:

isRenderableSupported in class OperationDescriptorImpl

---

### validateArguments

```
public boolean validateArguments(java.awt.image.renderable.ParameterBlock args,  
                                 java.lang.StringBuffer msg)
```

Validates the input parameters.

In addition to the standard checks performed by the superclass method, this method checks that "shiftX" and "shiftY" are between 0 and the source image width and height, respectively.

#### Overrides:

validateArguments in class OperationDescriptorImpl

---

## javax.media.jai.operator Class PhaseDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.PhaseDescriptor
```

---

```
public class PhaseDescriptor
extends OperationDescriptorImpl
```

An `OperationDescriptor` describing the "Phase" operation.

The "Phase" operation computes the phase angle of each pixel of a complex image. The source image must have an even number of bands, with the even bands (0, 2, ...) representing the real parts and the odd bands (1, 3, ...) the imaginary parts of each complex pixel. The destination image has at most half the number of bands of the source image with each sample in a pixel representing the phase angle of the corresponding complex source sample. The angular values of the destination image are defined for a given sample by the pseudocode:

```
dst[x][y][b] = Math.atan2(src[x][y][2*b+1], src[x][y][2*b])
```

where the number of bands  $b$  varies from zero to one less than the number of bands in the destination image.

For integral image datatypes, the result will be rounded and scaled so the the "natural" arctangent range  $[-\pi, \pi]$  is remapped into the range  $[0, \text{MAX\_VALUE}]$ ; the result for floating point image datatypes is the value returned by the `atan2()` method.

"Phase" defines a `PropertyGenerator` that sets the "COMPLEX" property of the image to `java.lang.Boolean.FALSE`, which may be retrieved by calling the `getProperty()` method with "COMPLEX" as the property name.

### Resource List

Name	Value
GlobalName	Phase
LocalName	Phase
Vendor	com.sun.media.jai
Description	Computes the phase angle of each pixel of an image.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/PhaseDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/PhaseDescriptor.html</a>
Version	1.0

No parameters are needed for the "Phase" operation.

### PhaseDescriptor

```
public PhaseDescriptor()
    Constructor.
```

---

## Method Detail

## **isRenderableSupported**

public boolean **isRenderableSupported**()

Returns true since renderable operation is supported.

**Overrides:**

isRenderableSupported in class OperationDescriptorImpl

---

## **validateSources**

protected boolean **validateSources**(java.awt.image.renderable.ParameterBlock args,  
java.lang.StringBuffer msg)

Validates the input source.

In addition to the standard checks performed by the superclass method, this method checks that the source image has an even number of bands.

**Overrides:**

validateSources in class OperationDescriptorImpl

---

## **getPropertyGenerators**

public PropertyGenerator[] **getPropertyGenerators**()

Returns an array of PropertyGenerators implementing property inheritance for the "Phase" operation.

**Returns:**

An array of property generators.

**Overrides:**

getPropertyGenerators in class OperationDescriptorImpl

---

## javax.media.jai.operator Class PhasePropertyGenerator

```
java.lang.Object
|
+-- javax.media.jai.operator.PhasePropertyGenerator
```

---

class **PhasePropertyGenerator**  
extends java.lang.Object  
implements PropertyGenerator  
This property generator computes the properties for the operation "Phase" dynamically.

---

### Constructor Detail

#### PhasePropertyGenerator

```
public PhasePropertyGenerator()
    Constructor.
```

### Method Detail

#### getPropertyNames

```
public java.lang.String[] getPropertyNames()
    Returns the valid property names for the operation "Phase".
    Specified by:
        getPropertyNames in interface PropertyGenerator
```

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,
                                     RenderedOp op)

    Returns the specified property.
    Specified by:
        getProperty in interface PropertyGenerator
    Parameters:
        name - Property name.
```

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,
                                     RenderableOp op)

    Returns the specified property.
    Specified by:
        getProperty in interface PropertyGenerator
    Parameters:
        name - Property name.
```

---

## javax.media.jai.operator Class PiecewiseDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.PiecewiseDescriptor
```

---

```
public class PiecewiseDescriptor
    extends OperationDescriptorImpl
```

An `OperationDescriptor` describing the "Piecewise" operation.

The "Piecewise" operation performs a piecewise linear mapping of the pixel values of an image. The piecewise linear mapping is described by a set of breakpoints which are provided as an array of the form

```
float breakPoints[N][2][numBreakPoints]
```

where the value of *N* may be either unity or the number of bands in the source image. If *N* is unity then the same set of breakpoints will be applied to all bands in the image. The abscissas of the supplied breakpoints must be monotonically increasing.

The pixel values of the destination image are defined by the pseudocode:

```
if (src[x][y][b] < breakPoints[b][0][0]) {
    dst[x][y][b] = breakPoints[b][1][0];
} else if (src[x][y][b] > breakPoints[b][0][numBreakPoints-1]) {
    dst[x][y][b] = breakPoints[b][1][numBreakPoints-1];
} else {
    int i = 0;
    while(breakPoints[b][0][i+1] < src[x][y][b]) {
        i++;
    }
    dst[x][y][b] = breakPoints[b][1][i] +
        (src[x][y][b] - breakPoints[b][0][i])*
        (breakPoints[b][1][i+1] - breakPoints[b][1][i])/
        (breakPoints[b][0][i+1] - breakPoints[b][0][i]);
}
```

### Resource List

Name	Value

```

The parameter name list for this operation.

---

## paramDefaults

```
private static final java.lang.Object[] paramDefaults
```

The parameter default value list for this operation.

## Constructor Detail

### PiecewiseDescriptor

```
public PiecewiseDescriptor()
```

Constructor.

## Method Detail

### isRenderableSupported

```
public boolean isRenderableSupported()
```

Returns true since renderable operation is supported.

#### Overrides:

isRenderableSupported in class OperationDescriptorImpl

---

### validateArguments

```
public boolean validateArguments(java.awt.image.renderable.ParameterBlock args,  
                                 java.lang.StringBuffer msg)
```

Validates the input source and parameter.

In addition to the standard checks performed by the superclass method, this method checks that the number of bands in "breakPoints" is either 1 or the number of bands in the source image, the second breakpoint array dimension is 2, the third dimension is the same for abscissas and ordinates, and that the abscissas are monotonically increasing.

#### Overrides:

validateArguments in class OperationDescriptorImpl

javax.media.jai.operator

Class PolarToComplexDescriptor

public class **PolarToComplexDescriptor**  
extends OperationDescriptorImpl

An `OperationDescriptor` describing the "PolarToComplex" operation.

The "PolarToComplex" operation creates an image with complex-valued pixels from two images the respective pixel values of which represent the magnitude (modulus) and phase of the corresponding complex pixel in the destination image. The source images should have the same number of bands. The first source image contains the magnitude values and the second source image the phase values. The destination will have twice as many bands with the even-indexed bands (0, 2, ...) representing the real and the odd-indexed bands (1, 3, ...) the imaginary parts of each pixel. The pixel values of the destination image are defined for a given complex sample by the pseudocode:

```
dst[x][y][2*b]   = src0[x][y][b]*Math.cos(src1[x][y][b])
dst[x][y][2*b+1] = src0[x][y][b]*Math.sin(src1[x][y][b])
```

where the index *b* varies from zero to one less than the number of bands in the source images.

For phase images with integral data type, it is assumed that the actual phase angle is scaled from the range [-PI, PI] to the range [0, MAX\_VALUE] where MAX\_VALUE is the maximum value of the data type in question.

"PolarToComplex" defines a `PropertyGenerator` that sets the "COMPLEX" property of the image to `java.lang.Boolean.TRUE`, which may be retrieved by calling the `getProperty()` method with "COMPLEX" as the property name.

Resource List

Name	Value
GlobalName	PolarToComplex
LocalName	PolarToComplex
Vendor	com.sun.media.jai
Description	Computes a complex image from a magnitude and a phase image.

## javax.media.jai.operator Class RenderableDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.RenderableDescriptor
```

---

public class **RenderableDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Renderable" operation.

In renderable image mode the "Renderable" operation produces from a RenderedImage source a RenderableImage consisting of a "pyramid" of RenderedImages at progressively lower resolutions. This operation does not support rendered image mode.

Lower resolution images are produced by invoking the chain of operations specified via the "downSampler" parameter on the image at the next higher resolution level of the pyramid. The "downSampler" operation chain must adhere to the specifications described for the constructors of the ImageMIPMap class which accept this type of parameter. The "downSampler" operation chain must reduce the image width and height at each level of the pyramid. The default operation chain for "downSampler" is a low pass filtering implemented using a 5x5 separable kernel derived from the one-dimensional kernel

```
[ 0.05 0.25 0.40 0.25 0.05 ]
```

followed by downsampling by 2.

The number of levels in the pyramid will be such that the maximum of the width and height of the lowest resolution pyramid level is less than or equal to the value of the "maxLowResDim" parameter which must be positive.

The minimum X and Y coordinates and height in rendering-independent coordinates are supplied by the parameters "minX", "minY", and "height", respectively. The value of "height" must be positive. It is not necessary to supply a value for the rendering-independent width as this is derived by multiplying the supplied height by the aspect ratio (width divided by height) of the source RenderedImage.

### Resource List

## javax.media.jai.operator Class RescaleDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.RescaleDescriptor
```

---

public class **RescaleDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Rescale" operation.

The "Rescale" operation takes a rendered or renderable source image and maps the pixel values of an image from one range to another range by multiplying each pixel value by one of a set of constants and then adding another constant to the result of the multiplication. If the number of constants supplied is less than the number of bands of the destination, then the constant from entry 0 is applied to all the bands. Otherwise, a constant from a different entry is applied to each band. There must be at least one entry in each of the constants and offsets arrays.

The destination pixel values are defined by the pseudocode:

```
constant = (constants.length < dstNumBands) ?
            constants[0] : constants[b];
offset = (offsets.length < dstNumBands) ?
         offsets[0] : offsets[b];

dst[x][y][b] = src[x][y][b]*constant + offset;
```

The pixel arithmetic is performed using the data type of the destination image. By default, the destination will have the same data type as the source image unless an ImageLayout containing a SampleModel with a different data type is supplied as a rendering hint.

### Resource List

```

Returns the valid property names for the operation "Rotate".

**Specified by:**

getPropertyNames in interface PropertyGenerator

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,
                                   RenderedOp op)
```

Returns the specified property.

**Specified by:**

getProperty in interface PropertyGenerator

**Parameters:**

name - Property name.

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,
                                   RenderableOp op)
```

Returns null.

**Specified by:**

getProperty in interface PropertyGenerator

**Parameters:**

name - Property name.

---

## javax.media.jai.operator Class ScaleDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.ScaleDescriptor
```

---

public class **ScaleDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Scale" operation.

The "Scale" operation translates and resizes an image. For each pixel (x, y) of the destination, the source value at the fractional subpixel position ((x - xTrans)/xScale, (y - yTrans)/yScale) is constructed by means of an Interpolation object and written to the destination.

When applying scale factors of scale\_x, scale\_y to a source image with width of src\_width and height of src\_height, the resulting image is defined to have the following dimensions: dst\_width = src\_width \* scale\_x dst\_height = src\_height \* scale\_y

When interpolations which require padding the source such as Bilinear or Bicubic interpolation are specified, the source needs to be extended such that it has the extra pixels needed to compute all the destination pixels. This extension is performed via the BorderExtender class. The type of Border Extension can be specified as a RenderingHint to the JAI.create method.

If no Border Extension is specified, the source will not be extended. The scaled image size is still calculated according to the formula specified above. However since there isn't enough source to compute all the destination pixels, only that subset of the destination image's pixels, which can be computed, will be written in the destination. The rest of the destination will not be written.

Specifying a scale factor of greater than 1 increases the size of the image, specifying a scale factor between 0 and 1 (non-inclusive) decreases the size of an image. An IllegalArgumentException will be thrown if the specified scale factors are negative or equal to zero.

"Scale" defines a PropertyGenerator that performs an identical transformation on the "ROI" property of the source image, which can be retrieved by calling the getProperty method with "ROI" as the property name.

Returns true since renderable operation is supported.

#### Overrides:

isRenderableSupported in class OperationDescriptorImpl

---

## getPropertyGenerators

public PropertyGenerator[] **getPropertyGenerators**()

Returns an array of PropertyGenerators implementing property inheritance for the "Scale" operation.

**Returns:**

An array of property generators.

**Overrides:**

getPropertyGenerators in class OperationDescriptorImpl

---

## validateParameters

protected boolean **validateParameters**(java.awt.image.renderable.ParameterBlock args,  
java.lang.StringBuffer msg)

Validates the input parameters.

In addition to the standard checks performed by the superclass method, this method checks that "xScale" and "yScale" are both greater than 0.

**Overrides:**

validateParameters in class OperationDescriptorImpl

---

## getParamMinValue

public java.lang.Number **getParamMinValue**(int index)

Returns the minimum legal value of a specified numeric parameter for this operation.

For the minimum value of "xScale" and "yScale", this method returns 0. However, the scale factors must be a positive floating number and can not be 0.

**Overrides:**

getParamMinValue in class OperationDescriptorImpl

---

**Parameters:**

name - Property name.

---

---

## javax.media.jai.operator Class ShearDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.ShearDescriptor
```

---

public class **ShearDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Shear" operation.

The "Shear" operation shears an image either horizontally or vertically. For each pixel (x, y) of the destination, the source value at the fractional subpixel position (x', y') is constructed by means of an Interpolation object and written to the destination.

If the "shearDir" parameter is equal to SHEAR\_HORIZONTAL then  $x' = (x - xTrans - y * shear)$  and  $y' = y$ . If the "shearDir" parameter is equal to SHEAR\_VERTICAL then  $x' = x$  and  $y' = (y - yTrans - x * shear)$ .

"Shear" defines a PropertyGenerator that performs an identical transformation on the "ROI" property of the source image, which can be retrieved by calling the getProperty method with "ROI" as the property name.

## javax.media.jai.operator

### Class StreamDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.StreamDescriptor
```

---

public class **StreamDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "Stream" operation.

The Stream operation produces an image by decoding data from a `SeekableStream`. The allowable formats are those registered with the `com.sun.media.jai.codec.ImageCodec` class.

The allowable formats are those registered with the `com.sun.media.jai.codec.ImageCodec` class.

The second parameter contains an instance of `ImageDecodeParam` to be used during the decoding. It may be set to null in order to perform default decoding, or equivalently may be omitted.

**The classes in the `com.sun.media.jai.codec` package are not a committed part of the JAI API. Future releases of JAI will make use of new classes in their place. This class will change accordingly.**

#### Resource List

Name	Value
GlobalName	stream
LocalName	stream
Vendor	com.sun.media.jai
Description	Reads an image from a <code>SeekableStream</code> .

## javax.media.jai.operator Class SubtractConstDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.SubtractConstDescriptor
```

---

public class **SubtractConstDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "SubtractConst" operation.

The SubtractConst operation takes one rendered or renderable source image and an array of double constants, and subtracts a constant from every pixel of its corresponding band of the source. If the number of constants supplied is less than the number of bands of the destination, then the constant from entry 0 is applied to all the bands. Otherwise, a constant from a different entry is applied to each band.

By default, the destination image bounds, data type, and number of bands are the same as the source image. If the result of the operation underflows/overflows the minimum/maximum value supported by the destination data type, then it will be clamped to the minimum/maximum value respectively.

The destination pixel values are defined by the pseudocode:

```
if (constants.length < dstNumBands) {
    dst[x][y][b] = src[x][y][b] - constants[0];
} else {
    dst[x][y][b] = src[x][y][b] - constants[b];
}
```

## Constructor Detail

### SubtractConstDescriptor

public **SubtractConstDescriptor**()

Constructor.

## Method Detail

### isRenderableSupported

public boolean **isRenderableSupported**()

Returns true since renderable operation is supported.

**Overrides:**

isRenderableSupported in class OperationDescriptorImpl

---

### validateParameters

protected boolean **validateParameters**(java.awt.image.renderable.ParameterBlock args,  
java.lang.StringBuffer message)

Validates the input parameter.

In addition to the standard checks performed by the superclass method, this method checks that the length of the "constants" array is at least 1.

**Overrides:**

validateParameters in class OperationDescriptorImpl

---

## javax.media.jai.operator Class SubtractDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.SubtractDescriptor
```

---

public class **SubtractDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "Subtract" operation.

The Subtract operation takes two rendered images, and for every pair of pixels, one from each source image of the corresponding position and band, subtracts the pixel from the second source from the pixel from the first source. No additional parameters are required.

The two source images may have different numbers of bands and data types. By default, the destination image bounds are the intersection of the two source image bounds. If the sources don't intersect, the destination will have a width and height of 0.

The default number of bands of the destination image is equal to the smallest number of bands of the sources, and the data type is the smallest data type with sufficient range to cover the range of both source data types (not necessarily the range of their sums).

As a special case, if one of the source images has N bands ( $N > 1$ ), the other source has 1 band, and an `ImageLayout` hint is provided containing a destination `SampleModel` with K bands ( $1 < K \leq N$ ), then the single band of the 1-banded source is subtracted from or into each of the first K bands of the N-band source.

If the result of the operation underflows/overflows the minimum/maximum value supported by the destination data type, then it will be clamped to the minimum/maximum value respectively.

The destination pixel values are defined by the pseudocode:

```
dst[x][y][dstBand] = clamp(srcs[0][x][y][src0Band] -
                           srcs[1][x][y][src1Band]);
```

### Class SubtractFromConstDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.SubtractFromConstDescriptor
```

---

public class **SubtractFromConstDescriptor**  
extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "SubtractFromConst" operation.

The SubtractFromConst operation takes one rendered or renderable image and an array of double constants, and subtracts every pixel of the same band of the source from the constant from the corresponding array entry. If the number of constants supplied is less than the number of bands of the destination, then the constant from entry 0 is applied to all the bands. Otherwise, a constant from a different entry is applied to each band.

By default, the destination image bound, data type, and number of bands are the same as the source image. If the result of the operation underflows/overflows the minimum/maximum value supported by the destination data type, then it will be clamped to the minimum/maximum value respectively.

The destination pixel values are defined by the pseudocode:

```
if (constants.length < dstNumBands) {
    dst[x][y][b] = constants[0] - src[x][y][b];
} else {
    dst[x][y][b] = constants[b] - src[x][y][b];
}
```

## javax.media.jai.operator Class TIFFDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.TIFFDescriptor
```

---

```
public class TIFFDescriptor
extends OperationDescriptorImpl
```

An `OperationDescriptor` describing the "TIFF" operation.

The "TIFF" operation reads TIFF 6.0 data from an `SeekableStream`.

TIFF version 6.0 was finalized in June, 1992. Since that time there have been two technical notes extending the specification.

JAI's property inheritance mechanism has been designed to allow the tag information of a TIFF file, or other tagged file, to be made available to applications in a straightforward way. User code may additionally supply `PropertyGenerator` objects that allow tag information to be propagated through chains of operations.

TIFF extensions, such as GeoTIFF (see [The GeoTIFF Web Page](#) ), operate by defining additional private tags, usually referenced by a small number of globally registered TIFF tags. JAI allows such tags to be decoded into first-class tags by adding suitable `PropertyGenerator` objects.

The TIFF format consists of a short header that points to a linked list of Image File Directories (IFDs). An IFD is essentially a list of tags. The `TIFFDirectory` class encapsulates the set of common operations performed on an IFD. Each tag has a numeric value, a datatype, and a byte offset at which the tag's data may be found. This mechanism allows TIFF files to contain multiple images, each in its own IFD, and to order their contents flexibly since (apart from the header) nothing is required to appear at a fixed offset.

The following properties are provided by the TIFF reader from standard TIFF tags, shown here with their numerical values:

Name	Value	Name	Value	Name	Value
TIFF_NewSubfileType	254	TIFF_YPosition	287	TIFF_TargetPrinter	337
TIFF_SubfileType	255	TIFF_FreeOffsets	288	TIFF_ExtraSamples	338

TIFF_Orientation	274	TIFF_PrimaryChromaticities	319	TIFF_YCbCrSubSampling	530
TIFF_SamplesPerPixel	277	TIFF_ColorMap	320	TIFF_YCbCrPositioning	531
TIFF_RowsPerStrip	278	TIFF_HalftoneHints	321	TIFF_ReferenceBlackWhite	532
TIFF_StripByteCounts	279	TIFF_TileWidth	322	TIFF_Copyright	33432
TIFF_MinSampleValue	280	TIFF_TileLength	323	TIFF_ModelPixelScaleTag	33550
TIFF_MaxSampleValue	281	TIFF_TileOffsets	324	TIFF_ModelTransformationTag	33920
TIFF_XResolution	282	TIFF_TileByteCounts	325	TIFF_ModelTiepointTag	33922
TIFF_YResolution	283	TIFF_InkSet	332	TIFF_GeoKeyDirectoryTag	34735
TIFF_PlanarConfiguration	284	TIFF_InkNames	333	TIFF_GeoDoubleParamsTag	34736
TIFF_PageName	285	TIFF_NumberOfInks	334	TIFF_GeoAsciiParamsTag	34737
TIFF_XPosition	286	TIFF_DotRange	336	TIFF_Private	n/a

Non-standard tags are handled in TIFF by the inclusion of a tag with a number of 32768 or above. Any tag from this range is treated as an uninterpreted `TIFF_Private` tag, and its raw data is made available as a property of class `TIFFField`. A user-specified `PropertyGenerator` can then interpret this directory to produce comprehensible values.

Some TIFF extensions make use of a mechanism known as "private IFDs." A private IFD is one that is not referenced by the standard linked list of IFDs that starts in the file header. To a standard TIFF reader, it appears as an unreferenced area in the file. However, the byte offset of the private IFD is stored as the value of a private tag, allowing readers that understand the tag to locate and interpret the IFD.

The second parameter contains an instance of `TIFFDecodeParam` to be used during the decoding. It may be set to `null` in order to perform default decoding, or equivalently may be omitted.

**The classes in the `com.sun.media.jai.codec` package are not a committed part of the JAI API. Future releases of JAI will make use of new classes in their place. This class will change accordingly.**

#### Resource List

## javax.media.jai.operator Class ThresholdDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.ThresholdDescriptor
```

---

public class **ThresholdDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Threshold" operation.

The Threshold operation takes one rendered image, and maps all the pixels of this image whose value falls within a specified range to a specified constant. The range is specified by a low value and a high value.

If the number of elements supplied via the "high", "low", and "constants" arrays are less than the number of bands of the source image, then the element from entry 0 is applied to all the bands. Otherwise, the element from a different entry is applied to its corresponding band.

The destination pixel values are defined by the pseudocode:

```
lowVal = (low.length < dstNumBands) ?
         low[0] : low[b];
highVal = (high.length < dstNumBands) ?
         high[0] : high[b];
const = (constants.length < dstNumBands) ?
        constants[0] : constants[b];

if (src[x][y][b] >= lowVal && src[x][y][b] <= highVal) {
    dst[x][y][b] = const;
} else {
    dst[x][y][b] = src[x][y][b];
}
```

## javax.media.jai.operator

### Class TranslateDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.TranslateDescriptor
```

---

public class **TranslateDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "Translate" operation.

The "Translate" operation copies an image to a new location in the plane.

For each pixel (x, y) of the destination, the source value at the fractional subpixel position (x - xTrans, y - yTrans) is constructed by means of an Interpolation object and written to the destination. If both xTrans and yTrans are integral, the operation simply "wraps" its source image to change the image's position in the coordinate plane.

"Translate" defines a PropertyGenerator that performs an identical transformation on the "ROI" property of the source image, which can be retrieved by calling the getProperty method with "ROI" as the property name.

#### Resource List

---

## javax.media.jai.operator

### Class TransposeDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.TransposeDescriptor
```

---

public class **TransposeDescriptor**

extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "Transpose" operation.

The "Transpose" operation performs the following operations:

- Flip an image across an imaginary horizontal line that runs through the center of the image (`FLIP_VERTICAL`).
- Flip an image across an imaginary vertical line that runs through the center of the image (`FLIP_HORIZONTAL`).
- Flip an image across its main diagonal that runs from the upper left to the lower right corner (`FLIP_DIAGONAL`).
- Flip an image across its main antidiagonal that runs from the upper right to the lower left corner (`FLIP_ANTIDIAGONAL`).
- Rotate an image clockwise by 90, 180, or 270 degrees (`ROTATE_90`, `ROTATE_180`, `ROTATE_270`).

In all cases, the resulting image will have the same origin (as defined by the return values of its `getMinX()` and `getMinY()` methods) as the source image.

"Transpose" defines a `PropertyGenerator` that performs an identical transformation on the "ROI" property of the source image, which can be retrieved by calling the `getProperty` method with "ROI" as the property name.

---

## getPropertyGenerators

public PropertyGenerator[] **getPropertyGenerators**()

Returns an array of PropertyGenerators implementing property inheritance for the "Transpose" operation.

**Returns:**

An array of property generators.

**Overrides:**

getPropertyGenerators in class OperationDescriptorImpl

---

## getParamMinValue

public java.lang.Number **getParamMinValue**(int index)

Returns the minimum legal value of a specified numeric parameter for this operation.

**Overrides:**

getParamMinValue in class OperationDescriptorImpl

---

## getParamMaxValue

public java.lang.Number **getParamMaxValue**(int index)

Returns the maximum legal value of a specified numeric parameter for this operation.

**Overrides:**

getParamMaxValue in class OperationDescriptorImpl

---

## javax.media.jai.operator Class TransposePropertyGenerator

```
java.lang.Object
|
+-- javax.media.jai.operator.TransposePropertyGenerator
```

---

class **TransposePropertyGenerator**

extends java.lang.Object

implements PropertyGenerator

This property generator computes the properties for the operation "Transpose" dynamically.

---

### Constructor Detail

#### TransposePropertyGenerator

```
public TransposePropertyGenerator()
```

Constructor.

### Method Detail

#### getPropertyNames

```
public java.lang.String[] getPropertyNames()
```

Returns the valid property names for the operation "Transpose".

**Specified by:**

getPropertyNames in interface PropertyGenerator

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,  
                                     RenderedOp op)
```

Returns the specified property.

**Specified by:**

getProperty in interface PropertyGenerator

**Parameters:**

name - Property name.

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,  
                                     RenderableOp op)
```

Returns null.

**Specified by:**

getProperty in interface PropertyGenerator

**Parameters:**

name - Property name.

---

## javax.media.jai.operator Class URLDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.URLDescriptor
```

---

public class **URLDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "URL" operation.

The URL operation creates an output image whose source is specified by a Uniform Resource Locator (URL).

The allowable formats are those registered with the `com.sun.media.jai.codec.ImageCodec` class.

The second parameter contains an instance of `ImageDecodeParam` to be used during the decoding. It may be set to `null` in order to perform default decoding, or equivalently may be omitted.

**The classes in the `com.sun.media.jai.codec` package are not a committed part of the JAI API. Future releases of JAI will make use of new classes in their place. This class will change accordingly.**

### Resource List

Name	Value
GlobalName	fileload
LocalName	fileload
Vendor	com.sun.media.jai
Description	Reads an image from a file.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/URLDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/URLDescriptor.html</a>
Version	1.0
arg0Desc	The path of the file to read from.
arg1Desc	The <code>ImageDecodeParam</code> to use.

### Parameter List

Name	Class Type	Default Value
URL	<code>java.net.URL</code>	<code>NO_PARAMETER_DEFAULT</code>
param	<code>com.sun.media.jai.codec.ImageDecodeParam</code>	<code>null</code>

### **URLDescriptor**

```
public URLDescriptor()
```

Constructor.

---

## javax.media.jai.operator Class WarpDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|
+-- javax.media.jai.operator.WarpDescriptor
```

---

public class **WarpDescriptor**

extends OperationDescriptorImpl

An OperationDescriptor describing the "Warp" operation.

The "Warp" operation performs (possibly filtered) general warping on an image.

"Warp" defines a PropertyGenerator that performs an identical transformation on the "ROI" property of the source image, which can be retrieved by calling the getProperty method with "ROI" as the property name.

### Resource List

Name	Value
GlobalName	Warp
LocalName	Warp
Vendor	com.sun.media.jai
Description	Warps an image according to a specified Warp object.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/WarpDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/WarpDescriptor.html</a>
Version	1.0
arg0Desc	The Warp object.
arg1Desc	The interpolation method.

### Parameter List

Name	Class Type	Default Value
warp	javax.media.jai.Warp	NO_PARAMETER_DEFAULT
interpolation	javax.media.jai.Interpolation	InterpolationNearest

### See Also:

## paramClasses

private static final java.lang.Class[] **paramClasses**

The parameter class types for the "Warp" operation.

---

## paramDefaults

private static final java.lang.Object[] **paramDefaults**

The parameter default values for the "Warp" operation.

## Constructor Detail

### WarpDescriptor

public **WarpDescriptor**()

Constructor.

## Method Detail

### getPropertyGenerators

public PropertyGenerator[] **getPropertyGenerators**()

Returns an array of PropertyGenerators implementing property inheritance for the "Warp" operation.

**Returns:**

An array of property generators.

**Overrides:**

getPropertyGenerators in class OperationDescriptorImpl

---

## javax.media.jai.operator Class WarpPropertyGenerator

```
java.lang.Object
|
+-- javax.media.jai.operator.WarpPropertyGenerator
```

---

class **WarpPropertyGenerator**

extends java.lang.Object

implements PropertyGenerator

This property generator computes the properties for the operation "Warp" dynamically.

---

### Constructor Detail

#### WarpPropertyGenerator

```
public WarpPropertyGenerator()
```

Constructor.

### Method Detail

#### getPropertyNames

```
public java.lang.String[] getPropertyNames()
```

Returns the valid property names for the operation "Warp".

**Specified by:**

getPropertyNames in interface PropertyGenerator

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,
                                   RenderedOp op)
```

Returns the specified property.

**Specified by:**

getProperty in interface PropertyGenerator

**Parameters:**

name - Property name.

---

#### getProperty

```
public java.lang.Object getProperty(java.lang.String name,
                                   RenderableOp op)
```

Returns null.

**Specified by:**

getProperty in interface PropertyGenerator

**Parameters:**

name - Property name.

---

## javax.media.jai.operator Class XorConstDescriptor

```
java.lang.Object
|
+-- javax.media.jai.OperationDescriptorImpl
|   |
|   +-- javax.media.jai.operator.XorConstDescriptor
```

---

public class **XorConstDescriptor**  
extends OperationDescriptorImpl

An OperationDescriptor describing the "XorConst" operation.

The XorConst operation takes one rendered or renderable image and an array of integer constants, and performs a bit-wise logical "xor" between every pixel in the same band of the source and the constant from the corresponding array entry. If the number of constants supplied is less than the number of bands of the destination, then the constant from entry 0 is applied to all the bands. Otherwise, a constant from a different entry is applied to each band.

The source image must have an integral data type. By default, the destination image bound, data type, and number of bands are the same as the source image.

The following matrix defines the "xor" operation.

Logical "xor"

src	const	Result
0	0	0
0	1	1
1	0	1
1	1	0

The destination pixel values are defined by the pseudocode:

```
if (constants.length < dstNumBands) {
    dst[x][y][b] = src[x][y][b] ^ constants[0];
} else {
    dst[x][y][b] = src[x][y][b] ^ constants[b];
}
```

### Resource List

Name	Value
GlobalName	XorConst
LocalName	XorConst
Vendor	com.sun.media.jai
Description	Logically "xors" a rendered image with constants.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/XorConstDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/XorConstDescriptor.html</a>
Version	1.0
arg0Desc	The constants to logically "xor" with.

### Parameter List

Name	Class Type	Default Value
constants	int[]	NO_PARAMETER_DEFAULT

**See Also:**

OperationDescriptor

---

## Field Detail

### resources

```
private static final java.lang.String[][] resources
```

The resource strings that provide the general documentation and specify the parameter list for this operation.

---

### paramClasses

```
private static final java.lang.Class[] paramClasses
```

The parameter class list for this operation. The number of constants provided should be either 1, in which case this same constant is applied to all the source bands; or the same number as the source bands, in which case one constant is applied to each band.

---

### paramNames

```
private static final java.lang.String[] paramNames
```

The parameter name list for this operation.

---

### paramDefaults

```
private static final java.lang.Object[] paramDefaults
```

The parameter default value list for this operation.

---

## Constructor Detail

### XorConstDescriptor

```
public XorConstDescriptor()
```

Constructor.

---

## Method Detail

### isRenderableSupported

```
public boolean isRenderableSupported()
```

Returns true since renderable operation is supported.

**Overrides:**

isRenderableSupported in class OperationDescriptorImpl

---

### validateArguments

```
public boolean validateArguments(java.awt.image.renderable.ParameterBlock args,  
                                 java.lang.StringBuffer message)
```

Validates the input source and parameter.

In addition to the standard checks performed by the superclass method, this method checks that the source image has an integral data type and that "constants" has length at least 1.

**Overrides:**

validateArguments in class OperationDescriptorImpl

---

## javax.media.jai.operator Class XorDescriptor

```
java.lang.Object
|
+--javax.media.jai.OperationDescriptorImpl
|
+--javax.media.jai.operator.XorDescriptor
```

---

public class **XorDescriptor**

extends `OperationDescriptorImpl`

An `OperationDescriptor` describing the "Xor" operation.

The Xor operation takes two rendered or renderable images, and performs bit-wise logical "xor" on every pair of pixels, one from each source image of the corresponding position and band. No additional parameters are required.

Both source images must have integral data types. The two data types may be different.

Unless altered by an `ImageLayout` hint, the destination image bound is the intersection of the two source image bounds. If the two sources don't intersect, the destination will have a width and height of 0. The number of bands of the destination image is equal to the lesser number of bands of the sources, and the data type is the smallest data type with sufficient range to cover the range of both source data types.

The following matrix defines the "xor" operation.

Logical "xor"

src1	src2	Result
0	0	0
0	1	1
1	0	1
1	1	0

The destination pixel values are defined by the pseudocode:

```
dst[x][y][b] = srcs[0][x][y][b] ^ srcs[1][x][y][b];
```

### Resource List

Name	Value
GlobalName	Xor
LocalName	Xor
Vendor	com.sun.media.jai
Description	Logically "xors" two rendered images.
DocURL	<a href="http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/XorDescriptor.html">http://java.sun.com/products/java-media/jai/forDevelopers/jai-apidocs/javax/media/jai/operator/XorDescriptor.html</a>
Version	1.0

```
private static final java.lang.String[][] resources
```

The resource strings that provide the general documentation and specify the parameter list for this operation.

## Constructor Detail

### XorDescriptor

```
public XorDescriptor()
```

Constructor.

## Method Detail

### isRenderableSupported

```
public boolean isRenderableSupported()
```

Returns true since renderable operation is supported.

**Overrides:**

isRenderableSupported in class OperationDescriptorImpl

### validateSources

```
protected boolean validateSources(java.awt.image.renderable.ParameterBlock args,  
                                     java.lang.StringBuffer msg)
```

Validates the input sources.

In addition to the standard checks performed by the superclass method, this method checks that the source images are of integral data type.

**Overrides:**

validateSources in class OperationDescriptorImpl

---

## Package javax.media.jai.widget

### Interface Summary

<i>ViewportListener</i>	An interface used by the <code>ScrollingImagePanel</code> class to inform listeners of the current viewable area of the image.
-------------------------	--

### Class Summary

<b>ImageCanvas</b>	A simple output widget for a <code>RenderedImage</code> .
<b>JaiI18N</b>	
<b>ScrollingImagePanel</b>	An extension of <code>java.awt.Panel</code> that contains an <code>ImageCanvas</code> and vertical and horizontal scrollbars.

---

---

## javax.media.jai.widget Class ImageCanvas

```
java.lang.Object
|
+-- java.awt.Component
|   |
|   +-- java.awt.Canvas
|       |
|       +-- javax.media.jai.widget.ImageCanvas
```

---

public class **ImageCanvas**  
extends java.awt.Canvas

A simple output widget for a `RenderedImage`. `ImageCanvas` subclasses `java.awt.Canvas`, and can be used in any context that calls for a `Canvas`. It monitors resize and update events and automatically requests tiles from its source on demand. Any displayed area outside the image is displayed in grey.

There is currently no policy regarding what sorts of widgets, if any, will be part of JAI.

Due to the limitations of `BufferedImage`, only `TYPE_BYTE` of band 1, 2, 3, 4, and `TYPE_USHORT` of band 1, 2, 3 images can be displayed using this widget.

---

### Field Detail

#### **im**

protected java.awt.image.RenderedImage **im**  
The source `RenderedImage`.

---

#### **sampleModel**

protected java.awt.image.SampleModel **sampleModel**  
The image's `SampleModel`.

---

#### **colorModel**

protected java.awt.image.ColorModel **colorModel**  
The image's `ColorModel` or one we supply.

---

#### **minTileX**

protected int **minTileX**  
The image's min X tile.

---

#### **maxTileX**

protected int **maxTileX**  
The image's max X tile.

---

#### **minTileY**

protected int **minTileY**  
The image's min Y tile.

---

#### **maxTileY**

protected int **maxTileY**  
The image's max Y tile.

---

## **tileWidth**

protected int **tileWidth**  
The image's tile width.

---

## **tileHeight**

protected int **tileHeight**  
The image's tile height.

---

## **tileGridXOffset**

protected int **tileGridXOffset**  
The image's tile grid X offset.

---

## **tileGridYOffset**

protected int **tileGridYOffset**  
The image's tile grid Y offset.

---

## **imWidth**

protected int **imWidth**

---

## **imHeight**

protected int **imHeight**

---

## **padX**

protected int **padX**  
used to center image in it's container

---

## **padY**

protected int **padY**

---

## **drawBorder**

protected boolean **drawBorder**

---

## **originX**

protected int **originX**  
The pixel to display in the upper left corner or the canvas.

---

## **originY**

protected int **originY**  
The pixel to display in the upper left corner or the canvas.

---

## **canvasWidth**

protected int **canvasWidth**  
The width of the canvas.

---

## canvasHeight

protected int **canvasHeight**  
The height of the canvas.

---

## grayColor

private java.awt.Color **grayColor**

---

## backgroundColor

private java.awt.Color **backgroundColor**

### Constructor Detail

#### ImageCanvas

public **ImageCanvas**(java.awt.image.RenderedImage im,  
boolean drawBorder)

Constructs an ImageCanvas to display a RenderedImage.

**Parameters:**

im - a RenderedImage to be displayed.  
drawBorder - true if a raised border is desired.

---

#### ImageCanvas

public **ImageCanvas**(java.awt.image.RenderedImage im)

Constructs an ImageCanvas to display a RenderedImage.

**Parameters:**

im - a RenderedImage to be displayed.

---

### Method Detail

#### initialize

private void **initialize**()  
Initializes the ImageCanvas.

---

#### addNotify

public void **addNotify**()  
**Overrides:**  
addNotify in class java.awt.Canvas

---

#### set

public void **set**(java.awt.image.RenderedImage im)  
Changes the source image to a new RenderedImage.

---

#### setOrigin

public void **setOrigin**(int x,  
int y)  
Changes the pixel to set Origin at x,y

---

#### getXOrigin

public int **getXOrigin**()

---

## **getYOrigin**

```
public int getYOrigin()
```

---

## **getXPad**

```
public int getXPad()
```

---

## **getYPad**

```
public int getYPad()
```

---

## **getMinimumSize**

```
public java.awt.Dimension getMinimumSize()
```

### **Overrides:**

getMinimumSize in class java.awt.Component

---

## **getPreferredSize**

```
public java.awt.Dimension getPreferredSize()
```

### **Overrides:**

getPreferredSize in class java.awt.Component

---

## **getMaximumSize**

```
public java.awt.Dimension getMaximumSize()
```

### **Overrides:**

getMaximumSize in class java.awt.Component

---

## **setBounds**

```
public void setBounds(int x,  
                      int y,  
                      int width,  
                      int height)
```

Records a new size. Called by the AWT.

### **Overrides:**

setBounds in class java.awt.Component

---

## **XtoTileX**

```
private int XtoTileX(int x)
```

---

## **YtoTileY**

```
private int YtoTileY(int y)
```

---

## **TileXtoX**

```
private int TileXtoX(int tx)
```

---

## **TileYtoY**

```
private int TileYtoY(int ty)
```

---

## **update**

```
public void update(java.awt.Graphics g)
```

There is no need to erase prior to drawing, so we override the default update method to simply call paint().

### **Overrides:**

update in class java.awt.Component

---

## **paint**

```
public void paint(java.awt.Graphics g)
```

Paint the image onto a Graphics object. The painting is performed tile-by-tile, and includes a grey region covering the unused portion of image tiles as well as the general background.

### **Overrides:**

paint in class java.awt.Canvas

---

**javax.media.jai.widget**

## **Class JaiI18N**

java.lang.Object

|-- javax.media.jai.widget.JaiI18N

---

class **JaiI18N**

extends java.lang.Object

---

### **Field Detail**

#### **packageName**

static java.lang.String **packageName**

### **Constructor Detail**

#### **JaiI18N**

**JaiI18N()**

### **Method Detail**

#### **getString**

public static java.lang.String **getString**(java.lang.String key)

---

## javax.media.jai.widget Class ScrollingImagePanel

```
java.lang.Object
|
+-- java.awt.Component
|   |
|   +-- java.awt.Container
|       |
|       +-- java.awt.ScrollPane
|           |
|           +-- javax.media.jai.widget.ScrollingImagePanel
```

---

```
public class ScrollingImagePanel
extends java.awt.ScrollPane
implements java.awt.event AdjustmentListener, java.awt.event.ComponentListener, java.awt.event.MouseListener,
java.awt.event.MouseMotionListener
```

An extension of java.awt.Panel that contains an ImageCanvas and vertical and horizontal scrollbars. The origin of the ImageCanvas is set according to the value of the scrollbars. Additionally, the origin may be changed by dragging the mouse. The window cursor will be changed to Cursor.MOVE\_CURSOR for the duration of the drag.

Due to the limitations of BufferedImage, only TYPE\_BYTE of band 1, 2, 3, 4, and TYPE\_USHORT of band 1, 2, 3 images can be displayed using this widget.

---

### Field Detail

#### ic

```
protected ImageCanvas ic
```

The ImageCanvas we are controlling.

---

#### im

```
protected java.awt.image.RenderedImage im
```

The RenderedImage displayed by the ImageCanvas.

---

#### panelWidth

```
protected int panelWidth
```

The width of the panel.

---

#### panelHeight

```
protected int panelHeight
```

The height of the panel.

---

#### viewportListeners

```
protected java.util.Vector viewportListeners
```

Vector of ViewportListeners.

---

#### moveSource

```
protected java.awt.Point moveSource
```

The initial Point of a mouse drag.

---

## beingDragged

protected boolean **beingDragged**

True if we are in the middle of a mouse drag.

---

## defaultCursor

protected java.awt.Cursor **defaultCursor**

A place to save the cursor.

---

## Constructor Detail

### ScrollingImagePanel

```
public ScrollingImagePanel(java.awt.image.RenderedImage im,
                           int width,
                           int height)
```

Constructs a ScrollingImagePanel of a given size for a given RenderedImage.

---

## Method Detail

### addViewportListener

```
public void addViewportListener(ViewportListener l)
```

Adds the specified ViewportListener to the panel

---

### removeViewportListener

```
public void removeViewportListener(ViewportListener l)
```

Removes the specified ViewportListener

---

### notifyViewportListeners

```
private void notifyViewportListeners(int x,
                                     int y,
                                     int w,
                                     int h)
```

---

### getXOrigin

```
public int getXOrigin()
```

Returns the XOrigin of the image

---

### getYOrigin

```
public int getYOrigin()
```

Returns the YOrigin of the image

---

### setOrigin

```
public void setOrigin(int x,
                     int y)
```

Sets the image origin to a given (x, y) position. The scrollbars are updated appropriately.

---

### setCenter

```
public void setCenter(int x,
                     int y)
```

Set the center of the image to the given coordinates of the scroll window.

---

## **set**

public void **set**(java.awt.image.RenderedImage im)  
Sets the panel to display the specified image

---

## **getXCenter**

public int **getXCenter**()  
Returns the X co-ordinate of the image center.

---

## **getYCenter**

public int **getYCenter**()  
Returns the Y co-ordinate of the image center.

---

## **getPreferredSize**

public java.awt.Dimension **getPreferredSize**()  
Called by the AWT when instantiating the component.  
**Overrides:**  
getPreferredSize in class java.awt.Container

---

## **setBounds**

public void **setBounds**(int x,  
                        int y,  
                        int width,  
                        int height)  
Called by the AWT during instantiation and when events such as resize occur.  
**Overrides:**  
setBounds in class java.awt.Component

---

## **adjustmentValueChanged**

public void **adjustmentValueChanged**(java.awt.event AdjustmentEvent e)  
Called by the AWT when either scrollbar changes.  
**Specified by:**  
adjustmentValueChanged in interface java.awt.event AdjustmentListener

---

## **componentResized**

public void **componentResized**(java.awt.event.ComponentEvent e)  
Called when the ImagePanel is resized  
**Specified by:**  
componentResized in interface java.awt.event.ComponentListener

---

## **componentHidden**

public void **componentHidden**(java.awt.event.ComponentEvent e)  
Ignored  
**Specified by:**  
componentHidden in interface java.awt.event.ComponentListener

---

## **componentMoved**

public void **componentMoved**(java.awt.event.ComponentEvent e)  
Ignored  
**Specified by:**  
componentMoved in interface java.awt.event.ComponentListener

---

## **componentShown**

public void **componentShown**(java.awt.event.ComponentEvent e)

Ignored

**Specified by:**

componentShown in interface java.awt.event.ComponentListener

---

## **startDrag**

private void **startDrag**(java.awt.Point p)

Called at the beginning of a mouse drag.

---

## **updateDrag**

protected void **updateDrag**(java.awt.Point moveTarget)

Called for each point of a mouse drag.

---

## **endDrag**

private void **endDrag**()

Called at the end of a mouse drag.

---

## **mousePressed**

public void **mousePressed**(java.awt.event.MouseEvent me)

Called by the AWT when the mouse button is pressed.

**Specified by:**

mousePressed in interface java.awt.event.MouseListener

---

## **mouseDragged**

public void **mouseDragged**(java.awt.event.MouseEvent me)

Called by the AWT as the mouse is dragged.

**Specified by:**

mouseDragged in interface java.awt.event.MouseMotionListener

---

## **mouseReleased**

public void **mouseReleased**(java.awt.event.MouseEvent me)

Called by the AWT when the mouse button is released.

**Specified by:**

mouseReleased in interface java.awt.event.MouseListener

---

## **mouseExited**

public void **mouseExited**(java.awt.event.MouseEvent me)

Called by the AWT when the mouse leaves the component.

**Specified by:**

mouseExited in interface java.awt.event.MouseListener

---

## **mouseClicked**

public void **mouseClicked**(java.awt.event.MouseEvent me)

Ignored.

**Specified by:**

mouseClicked in interface java.awt.event.MouseListener

---

## **mouseMoved**

public void **mouseMoved**(java.awt.event.MouseEvent me)

Ignored.

**Specified by:**

mouseMoved in interface java.awt.event.MouseMotionListener

---

## **mouseEntered**

public void **mouseEntered**(java.awt.event.MouseEvent me)

Ignored.

**Specified by:**

mouseEntered in interface java.awt.event.MouseListener

---

**javax.media.jai.widget**  
**Interface ViewportListener**

---

public abstract interface **ViewportListener**

An interface used by the `ScrollingImagePanel` class to inform listeners of the current viewable area of the image.

**See Also:**

`ScrollingImagePanel`

---

<b>Method Detail</b>
----------------------

**setViewport**

```
public void setViewport(int x,  
                        int y,  
                        int width,  
                        int height)
```

Called to inform the listener of the currently viewable area of the source image.

**Parameters:**

x - The X coordinate of the upper-left corner of the current viewable area.  
y - The Y coordinate of the upper-left corner of the current viewable area.  
width - The width of the current viewable area in pixels.  
height - The height of the current viewable area in pixels.

---

## Package com.sun.media.jai.codec

Interface Summary	
<i>ImageDecodeParam</i>	An empty (marker) interface to be implemented by all image decoder parameter classes.
<i>ImageDecoder</i>	An interface describing objects that transform an InputStream into a BufferedImage or Raster.
<i>ImageEncodeParam</i>	An empty (marker) interface to be implemented by all image encoder parameter classes.
<i>ImageEncoder</i>	An interface describing objects that transform a BufferedImage or Raster into an OutputStream.
<i>StreamSegmentMapper</i>	An interface for use with the SegmentedSeekableStream class.

Class Summary	
<b>BMPEncodeParam</b>	An instance of ImageEncodeParam for encoding images in the BMP format.
<b>ByteArraySeekableStream</b>	A subclass of SeekableStream that takes input from an array of bytes.
<b>FileCacheSeekableStream</b>	A subclass of SeekableStream that may be used to wrap a regular InputStream.
<b>FileSeekableStream</b>	A subclass of SeekableStream that takes its input from a File or RandomAccessFile.
<b>ForwardSeekableStream</b>	A subclass of SeekableStream that may be used to wrap a regular InputStream efficiently.
<b>FPXDecodeParam</b>	An instance of ImageDecodeParam for decoding images in the FlashPIX format.
<b>ImageCodec</b>	An abstract class allowing the creation of image decoders and encoders.
<b>ImageDecoderImpl</b>	A partial implementation of the ImageDecoder interface useful for subclassing.
<b>ImageEncoderImpl</b>	A partial implementation of the ImageEncoder interface useful for subclassing.
<b>JaiI18N</b>	
<b>JPEGEncodeParam</b>	A class which encapsulates the most common functionality required for the parameters to a Jpeg encode operation.
<b>MemoryCacheSeekableStream</b>	A subclass of SeekableStream that may be used to wrap a regular InputStream.
<b>PNGDecodeParam</b>	An instance of ImageDecodeParam for decoding images in the PNG format.
<b>PNGEncodeParam</b>	An instance of ImageEncodeParam for encoding images in the PNG format.
<b>PNGEncodeParam.Gray</b>	
<b>PNGEncodeParam.Palette</b>	
<b>PNGEncodeParam.RGB</b>	
<b>PNGSuggestedPaletteEntry</b>	A class representing the fields of a PNG suggested palette entry.
<b>PNMEncodeParam</b>	An instance of ImageEncodeParam for encoding images in the PNM format.
<b>SectorStreamSegmentMapper</b>	An implementation of the StreamSegmentMapper interface for segments of equal length.
<b>SeekableStream</b>	An abstract subclass of java.io.InputStream that allows seeking within the input, similar to the RandomAccessFile class.
<b>SegmentedSeekableStream</b>	A SegmentedSeekableStream provides a view of a subset of another SeekableStream consisting of a series of segments with given starting positions in the source stream and lengths.
<b>StreamSegment</b>	A utility class representing a segment within a stream as a long starting position and an int length.
<b>StreamSegmentMapperImpl</b>	An implementation of the StreamSegmentMapper interface that requires an explicit list of the starting locations and lengths of the source segments.
<b>TIFFDecodeParam</b>	An instance of ImageDecodeParam for decoding images in the TIFF format.
<b>TIFFDirectory</b>	A class representing an Image File Directory (IFD) from a TIFF 6.0 stream.
<b>TIFFEncodeParam</b>	An instance of ImageEncodeParam for encoding images in the TIFF format.
<b>TIFFField</b>	A class representing a field in a TIFF 6.0 Image File Directory.

---

---

**com.sun.media.jai.codec**  
**Class BMPEncodeParam**

```
java.lang.Object
|
+--com.sun.media.jai.codec.BMPEncodeParam
```

---

```
public class BMPEncodeParam
    extends java.lang.Object
    implements ImageEncodeParam
```

An instance of `ImageEncodeParam` for encoding images in the BMP format.

This class allows for the specification of various parameters while encoding (writing) a BMP format image file. By default, the version used is `VERSION_3`, no compression is used, and the data layout is `bottom_up`, such that the pixels are stored in bottom-up order, the first scanline being stored last.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

## Field Detail

### VERSION\_2

```
public static final int VERSION_2
    Constant for BMP version 2.
```

---

### VERSION\_3

```
public static final int VERSION_3
    Constant for BMP version 3.
```

---

### VERSION\_4

```
public static final int VERSION_4
    Constant for BMP version 4.
```

---

### version

```
private int version
```

---

### compressed

```
private boolean compressed
```

---

### topDown

```
private boolean topDown
```

---

## Constructor Detail

### BMPEncodeParam

```
public BMPEncodeParam()
    Constructs an BMPEncodeParam object with default values for parameters.
```

---

## Method Detail

---

### **setVersion**

public void **setVersion**(int versionNumber)  
Sets the BMP version to be used.

---

### **getVersion**

public int **getVersion**()  
Returns the BMP version to be used.

---

### **setCompressed**

public void **setCompressed**(boolean compressed)  
If set, the data will be written out compressed, if possible.

---

### **isCompressed**

public boolean **isCompressed**()  
Returns the value of the parameter compressed.

---

### **setTopDown**

public void **setTopDown**(boolean topDown)  
If set, the data will be written out in a top-down manner, the first scanline being written first.

---

### **isTopDown**

public boolean **isTopDown**()  
Returns the value of the topDown parameter.

---

### **checkVersion**

private void **checkVersion**(int versionNumber)

---

## com.sun.media.jai.codec Class ByteArraySeekableStream

```
java.lang.Object
|
+--java.io.InputStream
|   |
|   +--com.sun.media.jai.codec.SeekableStream
|       |
|       +--com.sun.media.jai.codec.ByteArraySeekableStream
```

---

public class **ByteArraySeekableStream**  
extends `SeekableStream`

A subclass of `SeekableStream` that takes input from an array of bytes. Seeking backwards is supported. The `mark()` and `reset()` methods are supported.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

### Field Detail

#### **src**

private byte[] **src**  
Array holding the source data.

---

#### **offset**

private int **offset**  
The starting offset within the array.

---

#### **length**

private int **length**  
The length of the valid segment of the array.

---

#### **pointer**

private int **pointer**  
The current output position.

---

### Constructor Detail

#### **ByteArraySeekableStream**

```
public ByteArraySeekableStream(byte[] src,  
                               int offset,  
                               int length)  
    throws java.io.IOException
```

Constructs a `ByteArraySeekableStream` taking input from a given segment of an input byte array.

---

#### **ByteArraySeekableStream**

```
public ByteArraySeekableStream(byte[] src)  
    throws java.io.IOException
```

Constructs a `ByteArraySeekableStream` taking input from an entire input byte array.

---

### Method Detail

---

## canSeekBackwards

public boolean **canSeekBackwards**()

Returns true since this object supports seeking backwards.

**Overrides:**

canSeekBackwards in class SeekableStream

---

## getFilePointer

public long **getFilePointer**()

Returns the current offset in this stream.

**Returns:**

the offset from the beginning of the stream, in bytes, at which the next read occurs.

**Overrides:**

getFilePointer in class SeekableStream

---

## seek

public void **seek**(long pos)

Sets the offset, measured from the beginning of this stream, at which the next read occurs. Seeking backwards is allowed.

**Parameters:**

pos - the offset position, measured in bytes from the beginning of the stream, at which to set the stream pointer.

**Overrides:**

seek in class SeekableStream

---

## read

public int **read**()

Reads the next byte of data from the input array. The value byte is returned as an int in the range 0 to 255. If no byte is available because the end of the stream has been reached, the value -1 is returned.

**Overrides:**

read in class SeekableStream

---

## read

public int **read**(byte[] b,  
int off,  
int len)

Copies up to len bytes of data from the input array into an array of bytes. An attempt is made to copy as many as len bytes, but a smaller number may be copied, possibly zero. The number of bytes actually copied is returned as an integer.

If b is null, a NullPointerException is thrown.

If off is negative, or len is negative, or off+len is greater than the length of the array b, then an IndexOutOfBoundsException is thrown.

If len is zero, then no bytes are copied and 0 is returned; otherwise, there is an attempt to copy at least one byte. If no byte is available because the stream is at end of stream, the value -1 is returned; otherwise, at least one byte is copied into b.

The first byte copied is stored into element b[off], the next one into b[off+1], and so on. The number of bytes copied is, at most, equal to len. Let k be the number of bytes actually copied; these bytes will be stored in elements b[off] through b[off+k-1], leaving elements b[off+k] through b[off+len-1] unaffected.

In every case, elements b[0] through b[off] and elements b[off+len] through b[b.length-1] are unaffected.

**Parameters:**

b - the buffer into which the data is copied.

off - the start offset in array b at which the data is written.

len - the maximum number of bytes to copy.

**Returns:**

the total number of bytes read into the buffer, or -1 if there is no more data because the end of the stream has been reached.

**Overrides:**

read in class SeekableStream

---

## skipBytes

public int **skipBytes**(int n)

Attempts to skip over n bytes of input discarding the skipped bytes.

This method may skip over some smaller number of bytes, possibly zero. This may result from any of a number of conditions; reaching end of stream before n bytes have been skipped is only one possibility. This method never throws an `EOFException`. The actual number of bytes skipped is returned. If n is negative, no bytes are skipped.

**Parameters:**

n - the number of bytes to be skipped.

**Returns:**

the actual number of bytes skipped.

**Overrides:**

skipBytes in class `SeekableStream`

---

## close

public void **close**()

Does nothing.

**Overrides:**

close in class `java.io.InputStream`

---

## length

public long **length**()

Returns the number of valid bytes in the input array.

---

**com.sun.media.jai.codec**  
**Class FPXDecodeParam**

java.lang.Object  
|  
+--com.sun.media.jai.codec.FPXDecodeParam

---

public class **FPXDecodeParam**  
extends java.lang.Object  
implements ImageDecodeParam

An instance of ImageDecodeParam for decoding images in the FlashPIX format.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

## Field Detail

### resolution

private int **resolution**

## Constructor Detail

### FPXDecodeParam

public **FPXDecodeParam**()  
Constructs a default instance of FPXDecodeParam.

---

### FPXDecodeParam

public **FPXDecodeParam**(int resolution)  
Constructs an instance of FPXDecodeParam to decode a given resolution.  
**Parameters:**  
resolution - The resolution number to be decoded.

## Method Detail

### setResolution

public void **setResolution**(int resolution)  
Sets the resolution to be decoded.  
**Parameters:**  
resolution - The resolution number to be decoded.

---

### getResolution

public int **getResolution**()  
Returns the resolution to be decoded.

---

**com.sun.media.jai.codec**  
**Class FileCacheSeekableStream**

```
java.lang.Object
|
+--java.io.InputStream
|   |
|   +--com.sun.media.jai.codec.SeekableStream
|       |
|       +--com.sun.media.jai.codec.FileCacheSeekableStream
```

---

public final class **FileCacheSeekableStream**  
extends `SeekableStream`

A subclass of `SeekableStream` that may be used to wrap a regular `InputStream`. Seeking backwards is supported by means of a file cache. In circumstances that do not allow the creation of a temporary file (for example, due to security consideration or the absence of local disk), the `MemoryCacheSeekableStream` class may be used instead.

The `mark()` and `reset()` methods are supported.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

<b>Field Detail</b>
---------------------

**stream**

private java.io.InputStream **stream**  
The source stream.

---

**cacheFile**

private java.io.File **cacheFile**  
The cache File.

---

**cache**

private java.io.RandomAccessFile **cache**  
The cache as a `RandomAccessFile`.

---

**bufLen**

private int **bufLen**  
The length of the read buffer.

---

**buf**

private byte[] **buf**  
The read buffer.

---

**length**

private long **length**  
Number of bytes in the cache.

---

**pointer**

private long **pointer**  
Next byte to be read.

---

## foundEOF

private boolean **foundEOF**

True if we've encountered the end of the source stream.

## Constructor Detail

### FileCacheSeekableStream

```
public FileCacheSeekableStream(java.io.InputStream stream)
    throws java.io.IOException
```

Constructs a MemoryCacheSeekableStream that takes its source data from a regular InputStream. Seeking backwards is supported by means of an file cache.

An IOException will be thrown if the attempt to create the cache file fails for any reason.

## Method Detail

### readUntil

```
private long readUntil(long pos)
    throws java.io.IOException
```

Ensures that at least pos bytes are cached, or the end of the source is reached. The return value is equal to the smaller of pos and the length of the source file.

### canSeekBackwards

```
public boolean canSeekBackwards()
```

Returns true since all FileCacheSeekableStream instances support seeking backwards.

**Overrides:**

canSeekBackwards in class SeekableStream

### getFilePointer

```
public long getFilePointer()
```

Returns the current offset in this file.

**Returns:**

the offset from the beginning of the file, in bytes, at which the next read occurs.

**Overrides:**

getFilePointer in class SeekableStream

### seek

```
public void seek(long pos)
    throws java.io.IOException
```

Sets the file-pointer offset, measured from the beginning of this file, at which the next read occurs.

**Parameters:**

pos - the offset position, measured in bytes from the beginning of the file, at which to set the file pointer.

**Throws:**

java.io.IOException - if pos is less than 0 or if an I/O error occurs.

**Overrides:**

seek in class SeekableStream

### read

```
public int read()
    throws java.io.IOException
```

Reads the next byte of data from the input stream. The value byte is returned as an int in the range 0 to 255. If no byte is available because the end of the stream has been reached, the value -1 is returned. This method blocks until input data is available, the end of the stream is detected, or an exception is thrown.

**Returns:**

the next byte of data, or -1 if the end of the stream is reached.

**Throws:**

java.io.IOException - if an I/O error occurs.

**Overrides:**  
read in class `SeekableStream`

---

## read

```
public int read(byte[] b,  
               int off,  
               int len)  
    throws java.io.IOException
```

Reads up to `len` bytes of data from the input stream into an array of bytes. An attempt is made to read as many as `len` bytes, but a smaller number may be read, possibly zero. The number of bytes actually read is returned as an integer.

This method blocks until input data is available, end of file is detected, or an exception is thrown.

If `b` is null, a `NullPointerException` is thrown.

If `off` is negative, or `len` is negative, or `off+len` is greater than the length of the array `b`, then an `IndexOutOfBoundsException` is thrown.

If `len` is zero, then no bytes are read and 0 is returned; otherwise, there is an attempt to read at least one byte. If no byte is available because the stream is at end of file, the value -1 is returned; otherwise, at least one byte is read and stored into `b`.

The first byte read is stored into element `b[off]`, the next one into `b[off+1]`, and so on. The number of bytes read is, at most, equal to `len`. Let  $k$  be the number of bytes actually read; these bytes will be stored in elements `b[off]` through `b[off+k-1]`, leaving elements `b[off+k]` through `b[off+len-1]` unaffected.

In every case, elements `b[0]` through `b[off]` and elements `b[off+len]` through `b[b.length-1]` are unaffected.

If the first byte cannot be read for any reason other than end of file, then an `IOException` is thrown. In particular, an `IOException` is thrown if the input stream has been closed.

**Parameters:**

`b` - the buffer into which the data is read.  
`off` - the start offset in array `b` at which the data is written.  
`len` - the maximum number of bytes to read.

**Returns:**

the total number of bytes read into the buffer, or -1 if there is no more data because the end of the stream has been reached.

**Throws:**

`java.io.IOException` - if an I/O error occurs.

**Overrides:**

read in class `SeekableStream`

---

## close

```
public void close()  
    throws java.io.IOException
```

Closes this stream and releases any system resources associated with the stream.

**Throws:**

`java.io.IOException` - if an I/O error occurs.

**Overrides:**

close in class `java.io.InputStream`

---

## com.sun.media.jai.codec Class FileSeekableStream

```
java.lang.Object
|
+--java.io.InputStream
|   |
|   +--com.sun.media.jai.codec.SeekableStream
|       |
|       +--com.sun.media.jai.codec.FileSeekableStream
```

---

public class **FileSeekableStream**  
extends `SeekableStream`

A subclass of `SeekableStream` that takes its input from a `File` or `RandomAccessFile`. Backwards seeking is supported. The `mark()` and `reset()` methods are supported.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

### Field Detail

#### **file**

private java.io.RandomAccessFile **file**

---

#### **markPos**

private long **markPos**

---

#### **PAGE\_SHIFT**

private static final int **PAGE\_SHIFT**

---

#### **PAGE\_SIZE**

private static final int **PAGE\_SIZE**

---

#### **PAGE\_MASK**

private static final int **PAGE\_MASK**

---

#### **NUM\_PAGES**

private static final int **NUM\_PAGES**

---

#### **READ\_CACHE\_LIMIT**

private static final int **READ\_CACHE\_LIMIT**

---

#### **pageBuf**

private byte[][] **pageBuf**

---

#### **currentPage**

private int[] **currentPage**

---

## length

private long **length**

---

## pointer

private long **pointer**

---

## Constructor Detail

### FileSeekableStream

```
public FileSeekableStream(java.io.RandomAccessFile file)
                        throws java.io.IOException
    Constructs a FileSeekableStream from a RandomAccessFile.
```

---

### FileSeekableStream

```
public FileSeekableStream(java.io.File file)
                        throws java.io.IOException
    Constructs a FileSeekableStream from a File.
```

---

### FileSeekableStream

```
public FileSeekableStream(java.lang.String name)
                        throws java.io.IOException
    Constructs a FileSeekableStream from a String path name.
```

---

## Method Detail

### canSeekBackwards

```
public final boolean canSeekBackwards()
    Returns true since seeking backwards is supported.
Overrides:
    canSeekBackwards in class SeekableStream
```

---

### getFilePointer

```
public final long getFilePointer()
                        throws java.io.IOException
    Returns the current offset in this stream.
Returns:
    the offset from the beginning of the stream, in bytes, at which the next read occurs.
Throws:
    java.io.IOException - if an I/O error occurs.
Overrides:
    getFilePointer in class SeekableStream
```

---

### seek

```
public final void seek(long pos)
                        throws java.io.IOException
Overrides:
    seek in class SeekableStream
```

---

### skip

```
public final int skip(int n)
                        throws java.io.IOException
```

---

## readPage

```
private byte[] readPage(long pointer)
    throws java.io.IOException
```

---

## read

```
public final int read()
    throws java.io.IOException
```

Forwards the request to the real File.

**Overrides:**

read in class SeekableStream

---

## read

```
public final int read(byte[] b,
    int off,
    int len)
    throws java.io.IOException
```

Forwards the request to the real File.

**Overrides:**

read in class SeekableStream

---

## close

```
public final void close()
    throws java.io.IOException
```

Forwards the request to the real File.

**Overrides:**

close in class java.io.InputStream

---

## mark

```
public final void mark(int readLimit)
```

Marks the current file position for later return using the `reset()` method.

**Overrides:**

mark in class SeekableStream

---

## reset

```
public final void reset()
    throws java.io.IOException
```

Returns the file position to its position at the time of the immediately previous call to the `mark()` method.

**Overrides:**

reset in class SeekableStream

---

## markSupported

```
public boolean markSupported()
```

Returns true since marking is supported.

**Overrides:**

markSupported in class SeekableStream

---

## com.sun.media.jai.codec Class ForwardSeekableStream

```
java.lang.Object
|
+--java.io.InputStream
|   |
|   +--com.sun.media.jai.codec.SeekableStream
|       |
|       +--com.sun.media.jai.codec.ForwardSeekableStream
```

---

public class **ForwardSeekableStream**  
extends `SeekableStream`

A subclass of `SeekableStream` that may be used to wrap a regular `InputStream` efficiently. Seeking backwards is not supported.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

### Field Detail

#### **src**

private java.io.InputStream **src**  
The source `InputStream`.

---

#### **pointer**

long **pointer**  
The current position.

---

#### **markPos**

long **markPos**  
The marked position.

---

### Constructor Detail

#### **ForwardSeekableStream**

public **ForwardSeekableStream**(java.io.InputStream src)  
Constructs a `InputStreamForwardSeekableStream` from a regular `InputStream`.

---

### Method Detail

#### **read**

public final int **read**()  
throws java.io.IOException  
Forwards the request to the real `InputStream`.  
**Overrides:**  
read in class `SeekableStream`

---

#### **read**

public final int **read**(byte[] b,  
int off,  
int len)  
throws java.io.IOException  
Forwards the request to the real `InputStream`.  
**Overrides:**  
read in class `SeekableStream`

---

## skip

```
public final long skip(long n)
    throws java.io.IOException
```

Forwards the request to the real `InputStream`.

**Overrides:**

skip in class `java.io.InputStream`

---

## available

```
public final int available()
    throws java.io.IOException
```

Forwards the request to the real `InputStream`.

**Overrides:**

available in class `java.io.InputStream`

---

## close

```
public final void close()
    throws java.io.IOException
```

Forwards the request to the real `InputStream`.

**Overrides:**

close in class `java.io.InputStream`

---

## mark

```
public final void mark(int readLimit)
```

Forwards the request to the real `InputStream`.

**Overrides:**

mark in class `SeekableStream`

---

## reset

```
public final void reset()
    throws java.io.IOException
```

Forwards the request to the real `InputStream`.

**Overrides:**

reset in class `SeekableStream`

---

## markSupported

```
public boolean markSupported()
```

Forwards the request to the real `InputStream`.

**Overrides:**

markSupported in class `SeekableStream`

---

## canSeekBackwards

```
public final boolean canSeekBackwards()
```

Returns `false` since seeking backwards is not supported.

**Overrides:**

canSeekBackwards in class `SeekableStream`

---

## getFilePointer

```
public final long getFilePointer()
```

Returns the current position in the stream (bytes read).

**Overrides:**

getFilePointer in class `SeekableStream`

---

---

## **seek**

```
public final void seek(long pos)  
    throws java.io.IOException
```

Seeks forward to the given position in the stream. If `pos` is smaller than the current position as returned by `getFilePointer()`, nothing happens.

### **Overrides:**

`seek` in class `SeekableStream`

---

**com.sun.media.jai.codec**

## **Class ImageCodec**

java.lang.Object

|--com.sun.media.jai.codec.ImageCodec

---

public abstract class **ImageCodec**

extends java.lang.Object

An abstract class allowing the creation of image decoders and encoders. Instances of `ImageCodec` may be registered. Once a codec has been registered, the format name associated with it may be used as the name parameter in the `createImageEncoder()` and `createImageDecoder()` methods.

Additionally, subclasses of `ImageCodec` are able to perform recognition of their particular format, wither by inspection of a fixed-length file header or by arbitrary access to the source data stream.

Format recognition is performed by two variants of the `isFormatRecognized()` method. Which variant should be called is determined by the output of the codec's `getNumHeaderBytes()` method, which returns 0 if arbitrary access to the stream is required, and otherwise returns the number of header bytes required to recognize the format. Each subclass of `ImageCodec` needs to implement only one of the two variants.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

### **Field Detail**

```
private static final java.awt.image.ComponentColorModel colorModelRGBA32
```

### Constructor Detail

## ImageCodec

```
protected ImageCodec()
```

Allow only subclasses to instantiate this class.

### Method Detail

```
static void ()
```

Load the JPEG and PNM codecs.

---

## getCodec

```
public static ImageCodec getCodec(java.lang.String name)
```

Returns the ImageCodec associated with the given name. null is returned if no codec is registered with the given name. Case is not significant.

**Parameters:**

name - The name associated with the codec.

**Returns:**

The associated ImageCodec, or null.

---

## registerCodec

```
public static void registerCodec(ImageCodec codec)
```

Associates an ImageCodec with its format name, as determined by its getFormatName( ) method. Case is not significant. Any codec previously associated with the name is discarded.

**Parameters:**

codec - The ImageCodec object to be registered.

---

## unregisterCodec

```
public static void unregisterCodec(java.lang.String name)
```

Unregisters the ImageCodec object currently responsible for handling the named format. Case is not significant.

**Parameters:**

name - The name associated with the codec to be removed.

---

## getCodecs

```
public static java.util.Enumeration getCodecs()
```

Returns an Enumeration of all registered ImageCodec objects.

---

## createImageEncoder

```
public static ImageEncoder createImageEncoder(java.lang.String name,  
                                              java.io.OutputStream dst,  
                                              ImageEncodeParam param)
```

Returns an ImageEncoder object suitable for encoding to the supplied OutputStream, using the supplied ImageEncodeParam object.

**Parameters:**

- name - The name associated with the codec.
- dst - An OutputStream to write to.
- param - An instance of ImageEncodeParam suitable for use with the named codec, or null.

**Returns:**

An instance of ImageEncoder, or null.

---

## createImageDecoder

```
public static ImageDecoder createImageDecoder(java.lang.String name,  
                                              java.io.InputStream src,  
                                              ImageDecodeParam param)
```

Returns an ImageDecoder object suitable for decoding from the supplied InputStream, using the supplied ImageDecodeParam object.

**Parameters:**

- name - The name associated with the codec.
- src - An InputStream to read from.
- param - An instance of ImageDecodeParam suitable for use with the named codec, or null.

**Returns:**

An instance of ImageDecoder, or null.

---

## createImageDecoder

```
public static ImageDecoder createImageDecoder(java.lang.String name,  
                                              java.io.File src,  
                                              ImageDecodeParam param)  
                                              throws java.io.IOException
```

Returns an ImageDecoder object suitable for decoding from the supplied File, using the supplied ImageDecodeParam object.

**Parameters:**

- name - The name associated with the codec.
- src - A File to read from.
- param - An instance of ImageDecodeParam suitable for use with the named codec, or null.

**Returns:**

An instance of ImageDecoder, or null.

---

## createImageDecoder

```
public static ImageDecoder createImageDecoder(java.lang.String name,  
                                              SeekableStream src,  
                                              ImageDecodeParam param)
```

Returns an ImageDecoder object suitable for decoding from the supplied SeekableStream, using the supplied ImageDecodeParam object.

**Parameters:**

- name - The name associated with the codec.
- src - A SeekableStream to read from.
- param - An instance of ImageDecodeParam suitable for use with the named codec, or null.

**Returns:**

An instance of ImageDecoder, or null.

---

## vectorToStrings

```
private static java.lang.String[] vectorToStrings(java.util.Vector nameVec)
```

---

## getDecoderNames

public static java.lang.String[] **getDecoderNames**(SeekableStream src)

Returns an array of Strings indicating the names of registered ImageCodecs that may be appropriate for reading the given SeekableStream.

If the src SeekableStream does not support seeking backwards (that is, its canSeekBackwards() method returns false) then only FormatRecognizers that require only a fixed-length header will be checked.

If the src stream does not support seeking backwards, it must support marking, as determined by its markSupported() method.

**Parameters:**

src - A SeekableStream which optionally supports seeking backwards.

**Returns:**

An array of Strings.

**Throws:**

java.lang.IllegalArgumentException - if src supports neither seeking backwards nor marking.

---

## getEncoderNames

public static java.lang.String[] **getEncoderNames**(java.awt.image.RenderedImage im, ImageEncodeParam param)

Returns an array of Strings indicating the names of registered ImageCodecs that may be appropriate for writing the given RenderedImage, using the optional ImageEncodeParam, which may be null.

**Parameters:**

im - A RenderedImage to be encoded.

param - An ImageEncodeParam, or null.

**Returns:**

An array of Strings.

---

## getFormatName

public abstract java.lang.String **getFormatName**()

Returns the name of this image format.

**Returns:**

A String containing the name of the image format supported by this codec.

---

## getNumHeaderBytes

public int **getNumHeaderBytes**()

Returns the number of bytes of header needed to recognize the format, or 0 if an arbitrary number of bytes may be needed. The default implementation returns 0.

The return value must be a constant for all instances of each particular subclass of ImageCodec.

Although it is legal to always return 0, in some cases processing may be more efficient if the number of bytes needed is known in advance.

---

## isFormatRecognized

public boolean **isFormatRecognized**(byte[] header)

Returns true if the format is recognized in the initial portion of a stream. The header will be passed in as a byte array of length getNumHeaderBytes(). This method should be called only if getNumHeaderBytes() returns a value greater than 0.

The default implementation throws an exception to indicate that it should never be called.

**Parameters:**

header - An array of bytes containing the input stream header.

**Returns:**

true if the format is recognized.

---

## isFormatRecognized

public boolean **isFormatRecognized**(SeekableStream src)  
throws java.io.IOException

Returns true if the format is recognized in the input data stream. This method should be called only if getNumHeaderBytesNeeded() returns 0.

The source `SeekableStream` is guaranteed to support seeking backwards, and should be seeked to 0 prior to calling this method.

The default implementation throws an exception to indicate that it should never be called.

**Parameters:**

`src` - A `SeekableStream` containing the input data.

**Returns:**

`true` if the format is recognized.

---

## **getEncodeParamClass**

protected abstract `java.lang.Class` **getEncodeParamClass()**

Returns a `Class` object indicating the proper subclass of `ImageEncodeParam` to be used with this `ImageCodec`. If encoding is not supported by this codec, `null` is returned. If encoding is supported, but a parameter object is not used during encoding, `Object.class` is returned to signal this fact.

---

## **getDecodeParamClass**

protected abstract `java.lang.Class` **getDecodeParamClass()**

Returns a `Class` object indicating the proper subclass of `ImageDecodeParam` to be used with this `ImageCodec`. If encoding is not supported by this codec, `null` is returned. If decoding is supported, but a parameter object is not used during decoding, `Object.class` is returned to signal this fact.

---

## **createImageEncoder**

protected abstract `ImageEncoder` **createImageEncoder**(`java.io.OutputStream` `dst`,  
`ImageEncodeParam` `param`)

In a concrete subclass of `ImageCodec`, returns an implementation of the `ImageEncoder` interface appropriate for that codec.

**Parameters:**

`dst` - An `OutputStream` to write to.

`param` - An instance of `ImageEncoderParam` suitable for use with the `ImageCodec` subclass, or `null`.

**Returns:**

An instance of `ImageEncoder`.

---

## **canEncodeImage**

public abstract `boolean` **canEncodeImage**(`java.awt.image.RenderedImage` `im`,  
`ImageEncodeParam` `param`)

Returns `true` if the given image and encoder param object are suitable for encoding by this `ImageCodec`. For example, some codecs may only deal with images with a certain number of bands; an attempt to encode an image with an unsupported number of bands will fail.

**Parameters:**

`im` - a `RenderedImage` whose ability to be encoded is to be determined.

`param` - a suitable `ImageEncodeParam` object, or `null`.

---

## **createImageDecoder**

protected `ImageDecoder` **createImageDecoder**(`java.io.InputStream` `src`,  
`ImageDecodeParam` `param`)

Returns an implementation of the `ImageDecoder` interface appropriate for that codec. Subclasses of `ImageCodec` may override this method if they wish to accept data directly from an `InputStream`; otherwise, this method will convert the source into a backwards-seekable `SeekableStream` and call the appropriate version of `createImageDecoder` for that data type.

Instances of `ImageCodec` that do not require the ability to seek backwards in their source `SeekableStream` should override this method in order to avoid the default call to `SeekableStream.wrapInputStream(src, true)`.

**Parameters:**

`src` - An `InputStream` to read from.

`param` - An instance of `ImageDecodeParam` suitable for use with the `ImageCodec` subclass, or `null`.

**Returns:**

An instance of `ImageDecoder`.

---

## createImageDecoder

```
protected ImageDecoder createImageDecoder(java.io.File src,  
                                           ImageDecodeParam param)  
    throws java.io.IOException
```

Returns an implementation of the ImageDecoder interface appropriate for that codec. Subclasses of ImageCodec may override this method if they wish to accept data directly from a File; otherwise, this method will convert the source into a SeekableStream and call the appropriate version of createImageDecoder for that data type.

**Parameters:**

dst - A File to read from.

param - An instance of ImageDecodeParam suitable for use with the ImageCodec subclass, or null.

**Returns:**

An instance of ImageDecoder.

---

## createImageDecoder

```
protected abstract ImageDecoder createImageDecoder(SeekableStream src,  
                                                    ImageDecodeParam param)
```

In a concrete subclass of ImageCodec, returns an implementation of the ImageDecoder interface appropriate for that codec.

**Parameters:**

dst - A SeekableStream to read from.

param - An instance of ImageDecodeParam suitable for use with the ImageCodec subclass, or null.

**Returns:**

An instance of ImageDecoder.

---

## createGrayIndexColorModel

```
public static java.awt.image.ColorModel createGrayIndexColorModel(java.awt.image.SampleModel sm,  
                                                                    boolean blackIsZero)
```

A convenience methods to create an instance of IndexColorModel suitable for the given 1-banded SampleModel.

**Parameters:**

sm - a 1-banded SampleModel.

blackIsZero - true if the gray ramp should go from black to white, false otherwise.

---

## createComponentColorModel

```
public static java.awt.image.ColorModel createComponentColorModel(java.awt.image.SampleModel sm)
```

A convenience method to create an instance of ComponentColorModel suitable for use with the given SampleModel. The SampleModel should have a data type of DataBuffer.TYPE\_BYTE, TYPE\_USHORT, or TYPE\_INT and between 1 and 4 bands. Depending on the number of bands of the SampleModel, either a gray, gray+alpha, rgb, or rgb+alpha ColorModel is returned.

---

**com.sun.media.jai.codec**

## **Interface ImageDecodeParam**

**All Known Subinterfaces:**

ImageEncodeParam

**All Known Implementing Classes:**

TIFFDecodeParam, FPXDecodeParam, PNGDecodeParam

---

public abstract interface **ImageDecodeParam**

extends java.lang.Cloneable, java.io.Serializable

An empty (marker) interface to be implemented by all image decoder parameter classes.

**This interface is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

---

## **com.sun.media.jai.codec** **Interface ImageDecoder**

**All Known Implementing Classes:**  
ImageDecoderImpl

---

public abstract interface **ImageDecoder**

An interface describing objects that transform an InputStream into a BufferedImage or Raster.

**This interface is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

### **Method Detail**

#### **getParam**

public ImageDecodeParam **getParam()**

Returns the current parameters as an instance of the ImageDecodeParam interface. Concrete implementations of this interface will return corresponding concrete implementations of the ImageDecodeParam interface. For example, a JPEGImageDecoder will return an instance of JPEGDecodeParam.

---

#### **setParam**

public void **setParam**(ImageDecodeParam param)

Sets the current parameters to an instance of the ImageDecodeParam interface. Concrete implementations of ImageDecoder may throw a RuntimeException if the param argument is not an instance of the appropriate subclass or subinterface. For example, a JPEGImageDecoder will expect param to be an instance of JPEGDecodeParam.

---

#### **getInputStream**

public SeekableStream **getInputStream()**

Returns the SeekableStream associated with this ImageDecoder.

---

#### **getNumPages**

public int **getNumPages()**  
throws java.io.IOException

Returns the number of pages present in the current stream.

---

#### **decodeAsRaster**

public java.awt.image.Raster **decodeAsRaster()**  
throws java.io.IOException

Returns a Raster that contains the decoded contents of the SeekableStream associated with this ImageDecoder. Only the first page of a multi-page image is decoded.

---

#### **decodeAsRaster**

public java.awt.image.Raster **decodeAsRaster**(int page)  
throws java.io.IOException

Returns a Raster that contains the decoded contents of the SeekableStream associated with this ImageDecoder. The given page of a multi-page image is decoded. If the page does not exist, an IOException will be thrown. Page numbering begins at zero.

**Parameters:**

page - The page to be decoded.

---

## **decodeAsRenderedImage**

```
public java.awt.image.RenderedImage decodeAsRenderedImage()  
                                     throws java.io.IOException
```

Returns a RenderedImage that contains the decoded contents of the SeekableStream associated with this ImageDecoder. Only the first page of a multi-page image is decoded.

---

## **decodeAsRenderedImage**

```
public java.awt.image.RenderedImage decodeAsRenderedImage(int page)  
                                     throws java.io.IOException
```

Returns a RenderedImage that contains the decoded contents of the SeekableStream associated with this ImageDecoder. The given page of a multi-page image is decoded. If the page does not exist, an IOException will be thrown. Page numbering begins at zero.

**Parameters:**

page - The page to be decoded.

---

## com.sun.media.jai.codec Class ImageDecoderImpl

java.lang.Object  
|  
+--com.sun.media.jai.codec.ImageDecoderImpl

---

public abstract class **ImageDecoderImpl**  
extends java.lang.Object  
implements ImageDecoder

A partial implementation of the ImageDecoder interface useful for subclassing.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

### Field Detail

#### input

protected SeekableStream **input**  
The SeekableStream associated with this ImageEncoder.

---

#### param

protected ImageDecodeParam **param**  
The ImageDecodeParam object associated with this ImageEncoder.

---

### Constructor Detail

#### ImageDecoderImpl

public **ImageDecoderImpl**(SeekableStream input,  
ImageDecodeParam param)  
Constructs an ImageDecoderImpl with a given SeekableStream and ImageDecodeParam instance.

---

#### ImageDecoderImpl

public **ImageDecoderImpl**(java.io.InputStream input,  
ImageDecodeParam param)  
Constructs an ImageDecoderImpl with a given InputStream and ImageDecodeParam instance. The input parameter will be used to construct a ForwardSeekableStream; if the ability to seek backwards is required, the caller should construct an instance of SeekableStream and make use of the other constructor.

---

### Method Detail

#### getParam

public ImageDecodeParam **getParam**()  
Returns the current parameters as an instance of the ImageDecodeParam interface. Concrete implementations of this interface will return corresponding concrete implementations of the ImageDecodeParam interface. For example, a JPEGImageDecoder will return an instance of JPEGDecodeParam.  
**Specified by:**  
getParam in interface ImageDecoder

---

#### setParam

public void **setParam**(ImageDecodeParam param)  
Sets the current parameters to an instance of the ImageDecodeParam interface. Concrete implementations of ImageDecoder may throw a RuntimeException if the param argument is not an instance of the appropriate subclass or subinterface. For example, a JPEGImageDecoder will expect param to be an instance of JPEGDecodeParam.  
**Specified by:**  
setParam in interface ImageDecoder

---

## getInputStream

```
public SeekableStream getInputStream()
```

Returns the SeekableStream associated with this ImageDecoder.

**Specified by:**

getInputStream in interface ImageDecoder

---

## getNumPages

```
public int getNumPages()  
    throws java.io.IOException
```

Returns the number of pages present in the current stream. By default, the return value is 1. Subclasses that deal with multi-page formats should override this method.

**Specified by:**

getNumPages in interface ImageDecoder

---

## decodeAsRaster

```
public java.awt.image.Raster decodeAsRaster()  
    throws java.io.IOException
```

Returns a Raster that contains the decoded contents of the SeekableStream associated with this ImageDecoder. Only the first page of a multi-page image is decoded.

**Specified by:**

decodeAsRaster in interface ImageDecoder

---

## decodeAsRaster

```
public java.awt.image.Raster decodeAsRaster(int page)  
    throws java.io.IOException
```

Returns a Raster that contains the decoded contents of the SeekableStream associated with this ImageDecoder. The given page of a multi-page image is decoded. If the page does not exist, an IOException will be thrown. Page numbering begins at zero.

**Specified by:**

decodeAsRaster in interface ImageDecoder

**Parameters:**

page - The page to be decoded.

---

## decodeAsRenderedImage

```
public java.awt.image.RenderedImage decodeAsRenderedImage()  
    throws java.io.IOException
```

Returns a RenderedImage that contains the decoded contents of the SeekableStream associated with this ImageDecoder. Only the first page of a multi-page image is decoded.

**Specified by:**

decodeAsRenderedImage in interface ImageDecoder

---

## decodeAsRenderedImage

```
public abstract java.awt.image.RenderedImage decodeAsRenderedImage(int page)  
    throws java.io.IOException
```

Returns a RenderedImage that contains the decoded contents of the SeekableStream associated with this ImageDecoder. The given page of a multi-page image is decoded. If the page does not exist, an IOException will be thrown. Page numbering begins at zero.

**Specified by:**

decodeAsRenderedImage in interface ImageDecoder

**Parameters:**

page - The page to be decoded.

---

**com.sun.media.jai.codec**

## **Interface ImageEncodeParam**

**All Known Implementing Classes:**

BMPEncodeParam, PNGEncodeParam, TIFFEncodeParam, JPEGEncodeParam, PNMEncodeParam

---

public abstract interface **ImageEncodeParam**

extends ImageDecodeParam, java.lang.Cloneable, java.io.Serializable

An empty (marker) interface to be implemented by all image encoder parameter classes.

**This interface is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

---

**com.sun.media.jai.codec**

## **Interface ImageEncoder**

**All Known Implementing Classes:**

ImageEncoderImpl

---

public abstract interface **ImageEncoder**

An interface describing objects that transform a BufferedImage or Raster into an OutputStream.

**This interface is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

### **Method Detail**

---

#### **getParam**

public ImageEncodeParam **getParam()**

Returns the current parameters as an instance of the ImageEncodeParam interface. Concrete implementations of this interface will return corresponding concrete implementations of the ImageEncodeParam interface. For example, a JPEGImageEncoder will return an instance of JPEGEncodeParam.

---

#### **setParam**

public void **setParam**(ImageEncodeParam param)

Sets the current parameters to an instance of the ImageEncodeParam interface. Concrete implementations of ImageEncoder may throw a RuntimeException if the params argument is not an instance of the appropriate subclass or subinterface. For example, a JPEGImageEncoder will expect param to be an instance of JPEGEncodeParam.

---

#### **getOutputStream**

public java.io.OutputStream **getOutputStream()**

Returns the OutputStream associated with this ImageEncoder.

---

#### **encode**

public void **encode**(java.awt.image.Raster ras,  
                    java.awt.image.ColorModel cm)  
                    throws java.io.IOException

Encodes a Raster with a given ColorModel and writes the output to the OutputStream associated with this ImageEncoder.

---

#### **encode**

public void **encode**(java.awt.image.RenderedImage im)  
                    throws java.io.IOException

Encodes a RenderedImage and writes the output to the OutputStream associated with this ImageEncoder.

---

## com.sun.media.jai.codec Class ImageEncoderImpl

java.lang.Object  
|  
+--com.sun.media.jai.codec.ImageEncoderImpl

---

public abstract class **ImageEncoderImpl**  
extends java.lang.Object  
implements ImageEncoder

A partial implementation of the ImageEncoder interface useful for subclassing.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

### Field Detail

#### output

protected java.io.OutputStream **output**  
The OutputStream associated with this ImageEncoder.

---

#### param

protected ImageEncodeParam **param**  
The ImageEncodeParam object associated with this ImageEncoder.

---

### Constructor Detail

#### ImageEncoderImpl

public **ImageEncoderImpl**(java.io.OutputStream output,  
ImageEncodeParam param)  
Constructs an ImageEncoderImpl with a given OutputStream and ImageEncoderParam instance.

---

### Method Detail

#### getParam

public ImageEncodeParam **getParam**()  
Returns the current parameters as an instance of the ImageEncodeParam interface. Concrete implementations of this interface will return corresponding concrete implementations of the ImageEncodeParam interface. For example, a JPEGImageEncoder will return an instance of JPEGEncodeParam.  
**Specified by:**  
getParam in interface ImageEncoder

---

#### setParam

public void **setParam**(ImageEncodeParam param)  
Sets the current parameters to an instance of the ImageEncodeParam interface. Concrete implementations of ImageEncoder may throw a RuntimeException if the params argument is not an instance of the appropriate subclass or subinterface. For example, a JPEGImageEncoder will expect param to be an instance of JPEGEncodeParam.  
**Specified by:**  
setParam in interface ImageEncoder

---

#### getOutputStream

public java.io.OutputStream **getOutputStream**()  
Returns the OutputStream associated with this ImageEncoder.  
**Specified by:**  
getOutputStream in interface ImageEncoder

---

---

## encode

```
public void encode(java.awt.image.Raster ras,  
                  java.awt.image.ColorModel cm)  
    throws java.io.IOException
```

Encodes a Raster with a given ColorModel and writes the output to the OutputStream associated with this ImageEncoder.

**Specified by:**

encode in interface ImageEncoder

---

## encode

```
public abstract void encode(java.awt.image.RenderedImage im)  
    throws java.io.IOException
```

Encodes a RenderedImage and writes the output to the OutputStream associated with this ImageEncoder.

**Specified by:**

encode in interface ImageEncoder

---

**com.sun.media.jai.codec**  
**Class JPEGEncodeParam**

```
java.lang.Object
|
+--com.sun.media.jai.codec.JPEGEncodeParam
```

---

```
public class JPEGEncodeParam
    extends java.lang.Object
    implements ImageEncodeParam
```

A class which encapsulates the most common functionality required for the parameters to a Jpeg encode operation. It does not include all of the parameters of the `com.sun.image.codec.jpeg` classes. Users needing that additional functionality should use those classes directly, bearing in mind that they are part of an uncommitted non-core interface that may be modified or removed in the future. This class makes very simple assumptions about the image colorspaces. Images with a single band are assumed to be grayscale. Images with three bands are assumed to be RGB and are encoded to YCbCr.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

<b>Field Detail</b>
---------------------

**JPEG\_MAX\_BANDS**

```
private static int JPEG_MAX_BANDS
```

---

**hSamp**

```
private int[] hSamp
```

---

**vSamp**

```
private int[] vSamp
```

---

**qTab**

```
private int[][] qTab
```

---

**qTabSlot**

```
private int[] qTabSlot
```

---

**qual**

```
private float qual
```

---

**rstInterval**

```
private int rstInterval
```

---

**writeImageOnly**

```
private boolean writeImageOnly
```

---

**writeTablesOnly**

```
private boolean writeTablesOnly
```

---

## writeJFIFHeader

private boolean **writeJFIFHeader**

---

## qualitySet

private boolean **qualitySet**

---

## qTabSet

private boolean[] **qTabSet**

## Constructor Detail

### JPEGEncodeParam

public **JPEGEncodeParam**()

Constructs a JAI JPEGEncodeParam object with default settings.

## Method Detail

### setHorizontalSubsampling

public void **setHorizontalSubsampling**(int component,  
int subsample)

Sets the horizontal subsampling to be applied to an image band. Defaults to 1 for grayscale and (1,2,2) for RGB.

**Parameters:**

component - The band for which to set horizontal subsampling.  
subsample - The horizontal subsampling factor.

---

### getHorizontalSubsampling

public int **getHorizontalSubsampling**(int component)

Get the horizontal subsampling factor for a band.

**Parameters:**

component - The band of the image for which to retrieve subsampling.

**Returns:**

The horizontal subsampling factor to be applied to this band

---

### setVerticalSubsampling

public void **setVerticalSubsampling**(int component,  
int subsample)

Sets the vertical subsampling to be applied to an image band. Defaults to 1 for grayscale and (1,2,2) for RGB.

**Parameters:**

component - The band for which to set vertical subsampling.  
subsample - The vertical subsampling factor.

---

### getVerticalSubsampling

public int **getVerticalSubsampling**(int component)

Get the vertical subsampling factor for a band.

**Parameters:**

component - The band of the image for which to retrieve subsampling.

**Returns:**

The vertical subsampling factor to be applied to this band

---

### setLumaQTable

public void **setLumaQTable**(int[] qTable)

Sets the quantization table to be used for luminance data. This is a convenience method which explicitly sets the contents of quantization table 0. The length of the table must be 64. This disables any quality setting.

**Parameters:**

qTable - Quantization table values in "zig-zag" order.

---

**setChromaQTable**

```
public void setChromaQTable(int[] qTable)
```

Sets the quantization table to be used for chrominance data. This is a convenience method which explicitly sets the contents of quantization table 1. The length of the table must be 64. This method assumes that all chroma components will use the same table. This disables any quality setting.

**Parameters:**

qTable - Quantization table values in "zig-zag" order.

---

**setQTable**

```
public void setQTable(int component,
                     int tableSlot,
                     int[] qTable)
```

Sets a quantization table to be used for a component. This method allows up to four independent tables to be specified. This disables any quality setting.

**Parameters:**

component - The band to which this table applies.  
tableSlot - The table number that this table is assigned to (0 to 3).  
qTable - Quantization table values in "zig-zag" order.

---

**isQTableSet**

```
public boolean isQTableSet(int component)
```

Tests if a Quantization table has been set.

**Returns:**

Returns true if the specified quantization table has been set.

---

**getQTable**

```
public int[] getQTable(int component)
```

Retrieve the contents of the quantization table used for a component.

**Parameters:**

component - The band to which this table applies.

**Returns:**

The contents of the quantization table as a reference.

**Throws:**

java.lang.IllegalStateException - if table has not been previously set for this component.

---

**getQTableSlot**

```
public int getQTableSlot(int component)
```

Retrieve the quantization table slot used for a component.

**Parameters:**

component - The band to which this table slot applies.

**Returns:**

The table slot used for this band.

**Throws:**

java.lang.IllegalStateException - if table has not been previously set for this component.

---

**setRestartInterval**

```
public void setRestartInterval(int restartInterval)
```

Sets the restart interval in Minimum Coded Units (MCUs). This can be useful in some environments to limit the effect of bitstream errors to a single restart interval. The default is zero (no restart interval markers).

**Parameters:**

restartInterval - Number of MCUs between restart markers.

---

## getRestartInterval

public int **getRestartInterval**()

Gets the restart interval in Minimum Coded Units (MCUs).

**Returns:**

The restart interval in MCUs (0 if not set).

---

## setQuality

public void **setQuality**(float quality)

This creates new quantization tables that replace the currently installed quantization tables. The created quantization table varies from very high compression, very low quality, (0.0) to low compression, very high quality (1.0) based on the quality parameter.

At a quality level of 1.0 the table will be all 1's which will lead to no loss of data due to quantization (however chrominance subsampling, if used, and roundoff error in the DCT will still degrade the image some what).

The default setting is 0.75 which provides high quality while insuring a good compression ratio.

Some guidelines: 0.75 high quality  
0.5 medium quality  
0.25 low quality

**Parameters:**

quality - 0.0-1.0 setting of desired quality level.

---

## isQualitySet

public boolean **isQualitySet**()

Tests if the quality parameter has been set in this JPEGEncodeParam.

**Returns:**

True/false flag indicating if quality has been set.

---

## getQuality

public float **getQuality**()

Retrieve the quality setting for this encoding. This is a number between 0.0 and 1.0.

**Returns:**

The specified quality setting (0.75 if not set).

---

## setWriteTablesOnly

public void **setWriteTablesOnly**(boolean tablesOnly)

Instructs the encoder to write only the table data to the output stream. This is considered an abbreviated JPEG stream.

Defaults to false -- normally both tables and encoded image data are written.

**Parameters:**

tablesOnly - If true, only the tables will be written.

---

## getWriteTablesOnly

public boolean **getWriteTablesOnly**()

Retrieve the setting of the writeTablesOnly flag.

**Returns:**

The setting of the writeTablesOnly flag (false if not set).

---

## setWriteImageOnly

public void **setWriteImageOnly**(boolean imageOnly)

Controls whether the encoder writes only the compressed image data to the output stream. This is considered an abbreviated JPEG stream. Defaults to false -- normally both tables and compressed image data are written.

**Parameters:**

imageOnly - If true, only the compressed image will be written.

---

### **getWriteImageOnly**

public boolean **getWriteImageOnly**()

Retrieve the setting of the writeImageOnly flag.

**Returns:**

The setting of the writeImageOnly flag (false if not set).

---

### **setWriteJFIFHeader**

public void **setWriteJFIFHeader**(boolean writeJFIF)

Controls whether the encoder writes a JFIF header using the APP0 marker. By default an APP0 marker is written to create a JFIF file.

**Parameters:**

writeJFIF - If true, writes a JFIF header.

---

### **getWriteJFIFHeader**

public boolean **getWriteJFIFHeader**()

Retrieve the setting of the writeJFIF flag.

**Returns:**

The setting of the writeJFIF flag (true if not set).

---

**com.sun.media.jai.codec**

## **Class JaiI18N**

java.lang.Object

## **Class MemoryCacheSeekableStream**

```
java.lang.Object
|
+-- java.io.InputStream
|   |
|   +-- com.sun.media.jai.codec.SeekableStream
|       |
|       +-- com.sun.media.jai.codec.MemoryCacheSeekableStream
```

---

public final class **MemoryCacheSeekableStream**  
extends `SeekableStream`

A subclass of `SeekableStream` that may be used to wrap a regular `InputStream`. Seeking backwards is supported by means of an in-memory cache. For greater efficiency, `FileCacheSeekableStream` should be used in circumstances that allow the creation of a temporary file.

The `mark()` and `reset()` methods are supported.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

### **Field Detail**

#### **src**

```
private java.io.InputStream src
```

The source input stream.

---

#### **pointer**

```
private long pointer
```

Position of first unread byte.

---

#### **SECTOR\_SHIFT**

```
private static final int SECTOR_SHIFT
```

Log<sub>2</sub> of the sector size.

---

#### **SECTOR\_SIZE**

```
private static final int SECTOR_SIZE
```

The sector size.

---

#### **SECTOR\_MASK**

```
private static final int SECTOR_MASK
```

A mask to determine the offset within a sector.

---

#### **data**

```
private java.util.Vector data
```

A Vector of source sectors.

---

#### **sectors**

```
int sectors
```

Number of sectors stored.

---

## length

int **length**

Number of bytes read.

---

## foundEOS

boolean **foundEOS**

True if we've previously reached the end of the source stream

---

## Constructor Detail

### MemoryCacheSeekableStream

public **MemoryCacheSeekableStream**(java.io.InputStream src)

Constructs a `MemoryCacheSeekableStream` that takes its source data from a regular `InputStream`. Seeking backwards is supported by means of an in-memory cache.

---

## Method Detail

### readUntil

private long **readUntil**(long pos)  
throws java.io.IOException

Ensures that at least `pos` bytes are cached, or the end of the source is reached. The return value is equal to the smaller of `pos` and the length of the source stream.

---

### canSeekBackwards

public boolean **canSeekBackwards**()

Returns true since all `MemoryCacheSeekableStream` instances support seeking backwards.

**Overrides:**

`canSeekBackwards` in class `SeekableStream`

---

### getFilePointer

public long **getFilePointer**()

Returns the current offset in this file.

**Returns:**

the offset from the beginning of the file, in bytes, at which the next read occurs.

**Overrides:**

`getFilePointer` in class `SeekableStream`

---

### seek

public void **seek**(long pos)  
throws java.io.IOException

Sets the file-pointer offset, measured from the beginning of this file, at which the next read occurs.

**Parameters:**

`pos` - the offset position, measured in bytes from the beginning of the file, at which to set the file pointer.

**Throws:**

java.io.IOException - if `pos` is less than 0 or if an I/O error occurs.

**Overrides:**

`seek` in class `SeekableStream`

---

### read

public int **read**()  
throws java.io.IOException

Reads the next byte of data from the input stream. The value byte is returned as an `int` in the range 0 to 255. If no byte is available because the end of the stream has been reached, the value `-1` is returned. This method blocks until input data is available, the end of the stream is detected, or an exception is thrown.

**Returns:**  
the next byte of data, or -1 if the end of the stream is reached.

**Overrides:**  
read in class `SeekableStream`

---

## read

```
public int read(byte[] b,  
               int off,  
               int len)  
    throws java.io.IOException
```

Reads up to `len` bytes of data from the input stream into an array of bytes. An attempt is made to read as many as `len` bytes, but a smaller number may be read, possibly zero. The number of bytes actually read is returned as an integer.

This method blocks until input data is available, end of file is detected, or an exception is thrown.

If `b` is null, a `NullPointerException` is thrown.

If `off` is negative, or `len` is negative, or `off+len` is greater than the length of the array `b`, then an `IndexOutOfBoundsException` is thrown.

If `len` is zero, then no bytes are read and 0 is returned; otherwise, there is an attempt to read at least one byte. If no byte is available because the stream is at end of file, the value -1 is returned; otherwise, at least one byte is read and stored into `b`.

The first byte read is stored into element `b[off]`, the next one into `b[off+1]`, and so on. The number of bytes read is, at most, equal to `len`. Let  $k$  be the number of bytes actually read; these bytes will be stored in elements `b[off]` through `b[off+k-1]`, leaving elements `b[off+k]` through `b[off+len-1]` unaffected.

In every case, elements `b[0]` through `b[off]` and elements `b[off+len]` through `b[b.length-1]` are unaffected.

If the first byte cannot be read for any reason other than end of file, then an `IOException` is thrown. In particular, an `IOException` is thrown if the input stream has been closed.

**Parameters:**

`b` - the buffer into which the data is read.  
`off` - the start offset in array `b` at which the data is written.  
`len` - the maximum number of bytes to read.

**Returns:**

the total number of bytes read into the buffer, or -1 if there is no more data because the end of the stream has been reached.

**Overrides:**

read in class `SeekableStream`

---

## com.sun.media.jai.codec Class PNGDecodeParam

```
java.lang.Object
|
+--com.sun.media.jai.codec.PNGDecodeParam
```

---

public class **PNGDecodeParam**  
extends java.lang.Object  
implements ImageDecodeParam

An instance of ImageDecodeParam for decoding images in the PNG format. PNGDecodeParam allows several aspects of the decoding process for PNG images to be controlled. By default, decoding produces output images with the following properties:

Images with a bit depth of 8 or less use a `DataBufferByte` to hold the pixel data. 16-bit images use a `DataBufferUShort`.

Palette color images and non-transparent grayscale images with bit depths of 1, 2, or 4 will have a `MultiPixelPackedSampleModel` and an `IndexColorModel`. For palette color images, the `ColorModel` palette contains the red, green, blue, and optionally alpha palette information. For grayscale images, the palette is used to expand the pixel data to cover the range 0-255. The pixels are stored packed 8, 4, or 2 to the byte.

All other images are stored using a `PixelInterleavedSampleModel` with each sample of a pixel occupying its own byte or short within the `DataBuffer`. A `ComponentColorModel` is used which simply extracts the red, green, blue, gray, and/or alpha information from separate `DataBuffer` entries.

Five aspects of this process may be altered by means of methods in this class.

`setSuppressAlpha()` prevents an alpha channel from appearing in the output.

`setExpandPalette()` turns palette-color images into 3-or 4-channel full-color images.

`setOutput8BitGray()` causes 1, 2, or 4 bit grayscale images to be output in 8-bit form, using a `ComponentSampleModel` and `ComponentColorModel`.

`setDecodingExponent()` causes the output image to be gamma-corrected using a supplied output gamma value.

`setExpandGrayAlpha()` causes 2-channel gray/alpha (GA) images to be output as full-color (GGGA) images, which may simplify further processing and display.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

### Field Detail

#### suppressAlpha

```
private boolean suppressAlpha
```

---

#### expandPalette

```
private boolean expandPalette
```

---

#### output8BitGray

```
private boolean output8BitGray
```

---

#### performGammaCorrection

```
private boolean performGammaCorrection
```

---

#### userExponent

```
private float userExponent
```

---

## displayExponent

private float **displayExponent**

---

## expandGrayAlpha

private boolean **expandGrayAlpha**

---

## generateEncodeParam

private boolean **generateEncodeParam**

---

## encodeParam

private PNGEncodeParam **encodeParam**

---

### Constructor Detail

## PNGDecodeParam

public **PNGDecodeParam**()

Constructs a default instance of PNGDecodeParam.

### Method Detail

## getSuppressAlpha

public boolean **getSuppressAlpha**()

Returns true if alpha (transparency) will be prevented from appearing in the output.

---

## setSuppressAlpha

public void **setSuppressAlpha**(boolean suppressAlpha)

If set, no alpha (transparency) channel will appear in the output image.

The default is to allow transparency to appear in the output image.

---

## getExpandPalette

public boolean **getExpandPalette**()

Returns true if palette-color images will be expanded to produce full-color output.

---

## setExpandPalette

public void **setExpandPalette**(boolean expandPalette)

If set, palette color images (PNG color type 3) will be decoded into full-color (RGB) output images. The output image may have 3 or 4 channels, depending on the presence of transparency information.

The default is to output palette images using a single channel. The palette information is used to construct the output image's ColorModel.

---

## getOutput8BitGray

public boolean **getOutput8BitGray**()

Returns the current value of the 8-bit gray output parameter.

---

## setOutput8BitGray

public void **setOutput8BitGray**(boolean output8BitGray)

If set, grayscale images with a bit depth less than 8 (1, 2, or 4) will be output in 8 bit form. The output values will occupy the full 8-bit range. For example, gray values 0, 1, 2, and 3 of a 2-bit image will be output as 0, 85, 170, and 255.

The decoding of non-grayscale images and grayscale images with a bit depth of 8 or 16 are unaffected by this setting. The default is not to perform expansion. Grayscale images with a depth of 1, 2, or 4 bits will be represented using a `MultiPixelPackedSampleModel` and an `IndexColorModel`.

---

### **getPerformGammaCorrection**

`public boolean getPerformGammaCorrection()`

Returns true if gamma correction is to be performed on the image data. The default is true.

If gamma correction is to be performed, the `getUserExponent()` and `getDisplayExponent()` methods are used in addition to the gamma value stored within the file (or the default value of 1/2.2 used if no value is found) to produce a single exponent using the formula:

$$\text{decoding\_exponent} = \text{user\_exponent} / (\text{gamma\_from\_file} * \text{display\_exponent})$$

---

### **setPerformGammaCorrection**

`public void setPerformGammaCorrection(boolean performGammaCorrection)`

Turns gamma correction of the image data on or off.

---

### **getUserExponent**

`public float getUserExponent()`

Returns the current value of the user exponent parameter. By default, the user exponent is equal to 1.0F.

---

### **setUserExponent**

`public void setUserExponent(float userExponent)`

Sets the user exponent to a given value. The exponent must be positive. If not, an `IllegalArgumentException` will be thrown.

The output image pixels will be placed through a transformation of the form:

$$\begin{aligned} \text{sample} &= \text{integer\_sample} / (2^{\text{bitdepth}} - 1.0) \\ \text{decoding\_exponent} &= \text{user\_exponent} / (\text{gamma\_from\_file} * \text{display\_exponent}) \\ \text{output} &= \text{sample}^{\text{decoding\_exponent}} \end{aligned}$$

where `gamma_from_file` is the gamma of the file data, as determined by the `gAMA`, `sRGB`, and/or `iCCP` chunks, and `display_exponent` is the exponent of the intrinsic transfer curve of the display, generally 2.2.

Input files which do not specify any gamma are assumed to have a gamma of 1/2.2; such images may be displayed on a CRT with an exponent of 2.2 using the default user exponent of 1.0.

The user exponent may be used in order to change the effective gamma of a file. If a file has a stored gamma of X, but the decoder believes that the true file gamma is Y, setting a user exponent of Y/X will produce the same result as changing the file gamma.

This parameter affects the decoding of all image types.

**Throws:**

`java.lang.IllegalArgumentException` - if `userExponent` is negative.

---

### **getDisplayExponent**

`public float getDisplayExponent()`

Returns the current value of the display exponent parameter. By default, the display exponent is equal to 2.2F.

---

### **setDisplayExponent**

`public void setDisplayExponent(float displayExponent)`

Sets the display exponent to a given value. The exponent must be positive. If not, an `IllegalArgumentException` will be thrown.

The output image pixels will be placed through a transformation of the form:

$$\begin{aligned} \text{sample} &= \text{integer\_sample} / (2^{\text{bitdepth}} - 1.0) \\ \text{decoding\_exponent} &= \text{user\_exponent} / (\text{gamma\_from\_file} * \text{display\_exponent}) \\ \text{output} &= \text{sample}^{\text{decoding\_exponent}} \end{aligned}$$

where `gamma_from_file` is the gamma of the file data, as determined by the `gAMA`, `sRGB`, and/or `iCCP` chunks, and `user_exponent` is an additional user-supplied parameter.

Input files which do not specify any gamma are assumed to have a gamma of  $1/2.2$ ; such images should be decoding using the default display exponent of 2.2.

If an image is to be processed further before being displayed, it may be preferable to set the display exponent to 1.0 in order to produce a linear output image.

This parameter affects the decoding of all image types.

**Throws:**

java.lang.IllegalArgumentException - if userExponent is negative.

---

## getExpandGrayAlpha

public boolean **getExpandGrayAlpha**()

Returns the current setting of the gray/alpha expansion.

---

## setExpandGrayAlpha

public void **setExpandGrayAlpha**(boolean expandGrayAlpha)

If set, images containing one channel of gray and one channel of alpha (GA) will be output in a 4-channel format (GGGA). This produces output that may be simpler to process and display.

This setting affects both images of color type 4 (explicit alpha) and images of color type 0 (grayscale) that contain transparency information.

By default, no expansion is performed.

---

## getGenerateEncodeParam

public boolean **getGenerateEncodeParam**()

Returns true if an instance of PNGEncodeParam will be available after an image has been decoded via the getEncodeParam method.

---

## setGenerateEncodeParam

public void **setGenerateEncodeParam**(boolean generateEncodeParam)

If set, an instance of PNGEncodeParam will be available after an image has been decoded via the getEncodeParam method that encapsulates information about the contents of the PNG file. If not set, this information will not be recorded and getEncodeParam() will return null.

---

## getEncodeParam

public PNGEncodeParam **getEncodeParam**()

If getGenerateEncodeParam() is true, this method may be called after decoding has completed, and will return an instance of PNGEncodeParam containing information about the contents of the PNG file just decoded.

---

## setEncodeParam

public void **setEncodeParam**(PNGEncodeParam encodeParam)

Sets the current encoder param instance. This method is intended to be called by the PNG decoder and will overwrite the current instance returned by getEncodeParam.

---

**com.sun.media.jai.codec**  
**Class PNGEncodeParam.Gray**

```
java.lang.Object
|
+--com.sun.media.jai.codec.PNGEncodeParam
|   |
|   +--com.sun.media.jai.codec.PNGEncodeParam.Gray
```

---

```
public static class PNGEncodeParam.Gray
extends PNGEncodeParam
```

---

## Field Detail

### backgroundSet

```
private boolean backgroundSet
```

---

### backgroundPaletteGray

```
private int backgroundPaletteGray
```

---

### transparency

```
private int[] transparency
```

---

### bitShift

```
private int bitShift
```

---

### bitShiftSet

```
private boolean bitShiftSet
```

---

## Constructor Detail

### PNGEncodeParam.Gray

```
public PNGEncodeParam.Gray()
    Constructs an instance of PNGEncodeParam.Gray.
```

---

## Method Detail

### unsetBackground

```
public void unsetBackground()
    Suppresses the 'bKGD' chunk from being output.
Overrides:
    unsetBackground in class PNGEncodeParam
```

---

### isBackgroundSet

```
public boolean isBackgroundSet()
    Returns true if a 'bKGD' chunk will be output.
Overrides:
    isBackgroundSet in class PNGEncodeParam
```

---

## setBitDepth

public void **setBitDepth**(int bitDepth)

Sets the desired bit depth for a grayscale image. The bit depth must be one of 1, 2, 4, 8, or 16.

When encoding a source image of a greater bit depth, pixel values will be clamped to the smaller range after shifting by the value given by `getBitShift()`. When encoding a source image of a smaller bit depth, pixel values will be shifted and left-filled with zeroes.

**Overrides:**

setBitDepth in class PNGEncodeParam

---

## setBackgroundGray

public void **setBackgroundGray**(int gray)

Sets the suggested gray level of the background.

The 'bKGD' chunk will encode this information.

---

## getBackgroundGray

public int **getBackgroundGray**()

Returns the suggested gray level of the background.

If the background gray level has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Throws:**

`java.lang.IllegalStateException` - if the background gray level is not set.

---

## setTransparentGray

public void **setTransparentGray**(int transparentGray)

Sets the gray value to be used to denote transparency.

Setting this attribute will cause the alpha channel of the input image to be ignored.

The 'tRNS' chunk will encode this information.

---

## getTransparentGray

public int **getTransparentGray**()

Returns the gray value to be used to denote transparency.

If the transparent gray value has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Throws:**

`java.lang.IllegalStateException` - if the transparent gray value is not set.

---

## setBitShift

public void **setBitShift**(int bitShift)

Sets the desired bit shift for a grayscale image. Pixels in the source image will be shifted right by the given amount prior to being clamped to the maximum value given by the encoded image's bit depth.

---

## getBitShift

public int **getBitShift**()

Returns the desired bit shift for a grayscale image.

If the bit shift has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Throws:**

`java.lang.IllegalStateException` - if the bit shift is not set.

---

### **unsetBitShift**

public void **unsetBitShift**()

Suppresses the setting of the bit shift of a grayscale image. Pixels in the source image will not be shifted prior to encoding.

---

### **isBitShiftSet**

public boolean **isBitShiftSet**()

Returns true if the bit shift has been set.

---

### **isBitDepthSet**

public boolean **isBitDepthSet**()

Returns true if the bit depth has been set.

---

**com.sun.media.jai.codec**

## **Class PNGEncodeParam.Palette**

java.lang.Object

|--com.sun.media.jai.codec.PNGEncodeParam

    |--com.sun.media.jai.codec.PNGEncodeParam.Palette

---

public static class **PNGEncodeParam.Palette**  
extends PNGEncodeParam

---

### **Field Detail**

#### **backgroundSet**

private boolean **backgroundSet**

---

#### **palette**

private int[] **palette**

---

#### **paletteSet**

private boolean **paletteSet**

---

#### **backgroundPaletteIndex**

private int **backgroundPaletteIndex**

---

#### **transparency**

private int[] **transparency**

---

### **Constructor Detail**

#### **PNGEncodeParam.Palette**

public **PNGEncodeParam.Palette()**

Constructs an instance of PNGEncodeParam.Palette.

### **Method Detail**

#### **unsetBackground**

public void **unsetBackground()**

Suppresses the 'bKGD' chunk from being output.

**Overrides:**

unsetBackground in class PNGEncodeParam

---

#### **isBackgroundSet**

public boolean **isBackgroundSet()**

Returns true if a 'bKGD' chunk will be output.

**Overrides:**

isBackgroundSet in class PNGEncodeParam

---

## setBitDepth

```
public void setBitDepth(int bitDepth)
```

Sets the desired bit depth for a palette image. The bit depth must be one of 1, 2, 4, or 8, or else an `IllegalArgumentException` will be thrown.

**Overrides:**

setBitDepth in class `PNGEncodeParam`

---

## setPalette

```
public void setPalette(int[] rgb)
```

Sets the RGB palette of the image to be encoded. The `rgb` parameter contains alternating R, G, B values for each color index used in the image. The number of elements must be a multiple of 3 between 3 and 3\*256.

The 'PLTE' chunk will encode this information.

**Parameters:**

`rgb` - An array of ints.

---

## getPalette

```
public int[] getPalette()
```

Returns the current RGB palette.

If the palette has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Returns:**

An array of ints.

**Throws:**

`java.lang.IllegalStateException` - if the palette is not set.

---

## unsetPalette

```
public void unsetPalette()
```

Suppresses the 'PLTE' chunk from being output.

---

## isPaletteSet

```
public boolean isPaletteSet()
```

Returns true if a 'PLTE' chunk will be output.

---

## setBackgroundPaletteIndex

```
public void setBackgroundPaletteIndex(int index)
```

Sets the palette index of the suggested background color.

The 'bKGD' chunk will encode this information.

---

## getBackgroundPaletteIndex

```
public int getBackgroundPaletteIndex()
```

Returns the palette index of the suggested background color.

If the background palette index has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Throws:**

`java.lang.IllegalStateException` - if the palette index is not set.

---

## setPaletteTransparency

```
public void setPaletteTransparency(byte[] alpha)
```

Sets the alpha values associated with each palette entry. The `alpha` parameter should have as many entries as there are RGB triples in the palette.

The 'tRNS' chunk will encode this information.

---

## **getPaletteTransparency**

`public byte[] getPaletteTransparency()`

Returns the alpha values associated with each palette entry.

If the palette transparency has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Throws:**

`java.lang.IllegalStateException` - if the palette transparency is not set.

---

**com.sun.media.jai.codec**  
**Class PNGEncodeParam.RGB**

```
java.lang.Object
|
+--com.sun.media.jai.codec.PNGEncodeParam
|   |
|   +--com.sun.media.jai.codec.PNGEncodeParam.RGB
```

---

public static class **PNGEncodeParam.RGB**  
extends PNGEncodeParam

---

## Field Detail

### backgroundSet

private boolean **backgroundSet**

---

### backgroundRGB

private int[] **backgroundRGB**

---

### transparency

private int[] **transparency**

---

## Constructor Detail

### PNGEncodeParam.RGB

public **PNGEncodeParam.RGB**()  
Constructs an instance of PNGEncodeParam.RGB.

---

## Method Detail

### unsetBackground

public void **unsetBackground**()  
Suppresses the 'bKGD' chunk from being output.  
**Overrides:**  
unsetBackground in class PNGEncodeParam

---

### isBackgroundSet

public boolean **isBackgroundSet**()  
Returns true if a 'bKGD' chunk will be output.  
**Overrides:**  
isBackgroundSet in class PNGEncodeParam

---

### setBitDepth

public void **setBitDepth**(int bitDepth)  
Sets the desired bit depth for an RGB image. The bit depth must be 8 or 16.  
**Overrides:**  
setBitDepth in class PNGEncodeParam

---

## **setBackgroundRGB**

```
public void setBackgroundRGB(int[] rgb)
```

Sets the RGB value of the suggested background color. The `rgb` parameter should have 3 entries. The 'bKGD' chunk will encode this information.

---

## **getBackgroundRGB**

```
public int[] getBackgroundRGB()
```

Returns the RGB value of the suggested background color.

If the background color has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Throws:**

`java.lang.IllegalStateException` - if the background color is not set.

---

## **setTransparentRGB**

```
public void setTransparentRGB(int[] transparentRGB)
```

Sets the RGB value to be used to denote transparency.

Setting this attribute will cause the alpha channel of the input image to be ignored.

The 'tRNS' chunk will encode this information.

---

## **getTransparentRGB**

```
public int[] getTransparentRGB()
```

Returns the RGB value to be used to denote transparency.

If the transparent color has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Throws:**

`java.lang.IllegalStateException` - if the transparent color is not set.

---

**com.sun.media.jai.codec**  
**Class PNGEncodeParam**

java.lang.Object  
|  
+--com.sun.media.jai.codec.PNGEncodeParam

**Direct Known Subclasses:**  
PNGEncodeParam.Gray, PNGEncodeParam.Palette, PNGEncodeParam.RGB

---

public abstract class **PNGEncodeParam**  
extends java.lang.Object  
implements ImageEncodeParam

An instance of ImageEncodeParam for encoding images in the PNG format.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

<b>Field Detail</b>
---------------------

**INTENT\_PERCEPTUAL**

public static final int **INTENT\_PERCEPTUAL**  
Constant for use with the sRGB chunk.

---

**INTENT\_RELATIVE**

public static final int **INTENT\_RELATIVE**  
Constant for use with the sRGB chunk.

---

**INTENT\_SATURATION**

public static final int **INTENT\_SATURATION**  
Constant for use with the sRGB chunk.

---

**INTENT\_ABSOLUTE**

public static final int **INTENT\_ABSOLUTE**  
Constant for use with the sRGB chunk.

---

**PNG\_FILTER\_NONE**

public static final int **PNG\_FILTER\_NONE**  
Constant for use in filtering.

---

**PNG\_FILTER\_SUB**

public static final int **PNG\_FILTER\_SUB**  
Constant for use in filtering.

---

**PNG\_FILTER\_UP**

public static final int **PNG\_FILTER\_UP**  
Constant for use in filtering.

---

## **PNG\_FILTER\_AVERAGE**

public static final int **PNG\_FILTER\_AVERAGE**  
Constant for use in filtering.

---

## **PNG\_FILTER\_PAETH**

public static final int **PNG\_FILTER\_PAETH**  
Constant for use in filtering.

---

## **bitDepth**

protected int **bitDepth**

---

## **bitDepthSet**

protected boolean **bitDepthSet**

---

## **useInterlacing**

private boolean **useInterlacing**

---

## **chromaticity**

private float[] **chromaticity**

---

## **chromaticitySet**

private boolean **chromaticitySet**

---

## **gamma**

private float **gamma**

---

## **gammaSet**

private boolean **gammaSet**

---

## **paletteHistogram**

private int[] **paletteHistogram**

---

## **paletteHistogramSet**

private boolean **paletteHistogramSet**

---

## **ICCProfileData**

private byte[] **ICCProfileData**

---

## **ICCProfileDataSet**

private boolean **ICCProfileDataSet**

---

## **physicalDimension**

private int[] **physicalDimension**

---

## **physicalDimensionSet**

private boolean **physicalDimensionSet**

---

## **suggestedPalette**

private PNGSuggestedPaletteEntry[] **suggestedPalette**

---

## **suggestedPaletteSet**

private boolean **suggestedPaletteSet**

---

## **significantBits**

private int[] **significantBits**

---

## **significantBitsSet**

private boolean **significantBitsSet**

---

## **SRGBIntent**

private int **SRGBIntent**

---

## **SRGBIntentSet**

private boolean **SRGBIntentSet**

---

## **text**

private java.lang.String[] **text**

---

## **textSet**

private boolean **textSet**

---

## **modificationTime**

private java.util.Date **modificationTime**

---

## **modificationTimeSet**

private boolean **modificationTimeSet**

---

## **transparencySet**

boolean **transparencySet**

---

## **zText**

private java.lang.String[] **zText**

---

private boolean **zTextSet**

---

## chunkType

java.util.Vector **chunkType**

---

## chunkData

java.util.Vector **chunkData**

---

### Constructor Detail

## PNGEncodeParam

public **PNGEncodeParam**()

---

### Method Detail

## getDefaultEncodeParam

public static PNGEncodeParam **getDefaultEncodeParam**(java.awt.image.RenderedImage im)

Returns an instance of PNGEncodeParam.Palette, PNGEncodeParam.Gray, or PNGEncodeParam.RGB appropriate for encoding the given image.

If the image has an IndexColorModel, an instance of PNGEncodeParam.Palette is returned. Otherwise, if the image has 1 or 2 bands an instance of PNGEncodeParam.Gray is returned. In all other cases an instance of PNGEncodeParam.RGB is returned.

Note that this method does not provide any guarantee that the given image will be successfully encoded by the PNG encoder, as it only performs a very superficial analysis of the image structure.

---

## setBitDepth

public abstract void **setBitDepth**(int bitDepth)

Sets the desired bit depth of an image.

---

## getBitDepth

public int **getBitDepth**()

Returns the desired bit depth for a grayscale image.

If the bit depth has not previously been set, or has been unset, an IllegalStateException will be thrown.

**Throws:**

java.lang.IllegalStateException - if the bit depth is not set.

---

## unsetBitDepth

public void **unsetBitDepth**()

Suppresses the setting of the bit depth of a grayscale image. The depth of the encoded image will be inferred from the source image bit depth, rounded up to the next power of 2 between 1 and 16.

---

## setInterlacing

public void **setInterlacing**(boolean useInterlacing)

Turns Adam7 interlacing on or off.

---

## getInterlacing

public boolean **getInterlacing**()

Returns true if Adam7 interlacing will be used.

---

## unsetBackground

```
public void unsetBackground()
```

Suppresses the 'bKGD' chunk from being output. For API compatibility with JAI 1.0, the superclass defines this method to throw a `RuntimeException`; accordingly, subclasses must provide their own implementations.

---

## isBackgroundSet

```
public boolean isBackgroundSet()
```

Returns true if a 'bKGD' chunk will be output. For API compatibility with JAI 1.0, the superclass defines this method to throw a `RuntimeException`; accordingly, subclasses must provide their own implementations.

---

## setChromaticity

```
public void setChromaticity(float[] chromaticity)
```

Sets the white point and primary chromaticities in CIE (x, y) space.

The `chromaticity` parameter should be a `float` array of length 8 containing the white point X and Y, red X and Y, green X and Y, and blue X and Y values in order.

The 'cHRM' chunk will encode this information.

---

## setChromaticity

```
public void setChromaticity(float whitePointX,  
                             float whitePointY,  
                             float redX,  
                             float redY,  
                             float greenX,  
                             float greenY,  
                             float blueX,  
                             float blueY)
```

A convenience method that calls the array version.

---

## getChromaticity

```
public float[] getChromaticity()
```

Returns the white point and primary chromaticities in CIE (x, y) space.

See the documentation for the `setChromaticity` method for the format of the returned data.

If the chromaticity has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Throws:**

`java.lang.IllegalStateException` - if the chromaticity is not set.

---

## unsetChromaticity

```
public void unsetChromaticity()
```

Suppresses the 'cHRM' chunk from being output.

---

## isChromaticitySet

```
public boolean isChromaticitySet()
```

Returns true if a 'cHRM' chunk will be output.

---

## setGamma

```
public void setGamma(float gamma)
```

Sets the file gamma value for the image.

The 'gAMA' chunk will encode this information.

---

## getGamma

public float **getGamma**()

Returns the file gamma value for the image.

If the file gamma has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Throws:**

`java.lang.IllegalStateException` - if the gamma is not set.

---

## unsetGamma

public void **unsetGamma**()

Suppresses the 'gAMA' chunk from being output.

---

## isGammaSet

public boolean **isGammaSet**()

Returns true if a 'gAMA' chunk will be output.

---

## setPaletteHistogram

public void **setPaletteHistogram**(int[] paletteHistogram)

Sets the palette histogram to be stored with this image. The histogram consists of an array of integers, one per palette entry.

The 'hIST' chunk will encode this information.

---

## getPaletteHistogram

public int[] **getPaletteHistogram**()

Returns the palette histogram to be stored with this image.

If the histogram has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Throws:**

`java.lang.IllegalStateException` - if the histogram is not set.

---

## unsetPaletteHistogram

public void **unsetPaletteHistogram**()

Suppresses the 'hIST' chunk from being output.

---

## isPaletteHistogramSet

public boolean **isPaletteHistogramSet**()

Returns true if a 'hIST' chunk will be output.

---

## setICCProfileData

public void **setICCProfileData**(byte[] ICCProfileData)

Sets the ICC profile data to be stored with this image. The profile is represented in raw binary form.

The 'iCCP' chunk will encode this information.

---

## getICCProfileData

public byte[] **getICCProfileData**()

Returns the ICC profile data to be stored with this image.

If the ICC profile has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Throws:**

`java.lang.IllegalStateException` - if the ICC profile is not set.

---

## unsetICCProfileData

```
public void unsetICCProfileData()
```

Suppresses the 'iCCP' chunk from being output.

---

## isICCProfileDataSet

```
public boolean isICCProfileDataSet()
```

Returns true if a 'iCCP' chunk will be output.

---

## setPhysicalDimension

```
public void setPhysicalDimension(int[] physicalDimension)
```

Sets the physical dimension information to be stored with this image. The physicalDimension parameter should be a 3-entry array containing the number of pixels per unit in the X direction, the number of pixels per unit in the Y direction, and the unit specifier (0 = unknown, 1 = meters).

The 'pHYS' chunk will encode this information.

---

## setPhysicalDimension

```
public void setPhysicalDimension(int xPixelsPerUnit,  
                                int yPixelsPerUnit,  
                                int unitSpecifier)
```

A convenience method that calls the array version.

---

## getPhysicalDimension

```
public int[] getPhysicalDimension()
```

Returns the physical dimension information to be stored with this image.

If the physical dimension information has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Throws:**

- `java.lang.IllegalStateException` - if the physical dimension information is not set.

---

## unsetPhysicalDimension

```
public void unsetPhysicalDimension()
```

Suppresses the 'pHYS' chunk from being output.

---

## isPhysicalDimensionSet

```
public boolean isPhysicalDimensionSet()
```

Returns true if a 'pHYS' chunk will be output.

---

## setSuggestedPalette

```
public void setSuggestedPalette(PNGSuggestedPaletteEntry[] palette)
```

Sets the suggested palette information to be stored with this image. The information is passed to this method as an array of `PNGSuggestedPaletteEntry` objects.

The 'sPLT' chunk will encode this information.

---

## getSuggestedPalette

```
public PNGSuggestedPaletteEntry[] getSuggestedPalette()
```

Returns the suggested palette information to be stored with this image.

If the suggested palette information has not previously been set, or has been unset, an `IllegalStateException` will be thrown.

**Throws:**

- `java.lang.IllegalStateException` - if the suggested palette information is not set.

---

## unsetSuggestedPalette

public void **unsetSuggestedPalette**()  
Suppresses the 'sPLT' chunk from being output.

---

## isSuggestedPaletteSet

public boolean **isSuggestedPaletteSet**()  
Returns true if a 'sPLT' chunk will be output.

---

## setSignificantBits

public void **setSignificantBits**(int[] significantBits)  
Sets the number of significant bits for each band of the image.  
The number of entries in the `significantBits` array must be equal to the number of output bands in the image: 1 for a gray image, 2 for gray+alpha, 3 for index or truecolor, and 4 for truecolor+alpha.  
The 'sBIT' chunk will encode this information.

---

## getSignificantBits

public int[] **getSignificantBits**()  
Returns the number of significant bits for each band of the image.  
If the significant bits values have not previously been set, or have been unset, an `IllegalStateException` will be thrown.  
**Throws:**  
    `java.lang.IllegalStateException` - if the significant bits values are not set.

---

## unsetSignificantBits

public void **unsetSignificantBits**()  
Suppresses the 'sBIT' chunk from being output.

---

## isSignificantBitsSet

public boolean **isSignificantBitsSet**()  
Returns true if an 'sBIT' chunk will be output.

---

## setSRGBIntent

public void **setSRGBIntent**(int sRGBIntent)  
Sets the sRGB rendering intent to be stored with this image. The legal values are 0 = Perceptual, 1 = Relative Colorimetric, 2 = Saturation, and 3 = Absolute Colorimetric. Refer to the PNG specification for information on these values.  
The 'sRGB' chunk will encode this information.

---

## getSRGBIntent

public int **getSRGBIntent**()  
Returns the sRGB rendering intent to be stored with this image.  
If the sRGB intent has not previously been set, or has been unset, an `IllegalStateException` will be thrown.  
**Throws:**  
    `java.lang.IllegalStateException` - if the sRGB intent is not set.

---

## unsetSRGBIntent

public void **unsetSRGBIntent**()  
Suppresses the 'sRGB' chunk from being output.

---

## isSRGBIntentSet

public boolean **isSRGBIntentSet**()  
Returns true if an 'sRGB' chunk will be output.

---

## setText

public void **setText**(java.lang.String[] text)  
Sets the textual data to be stored in uncompressed form with this image. The data is passed to this method as an array of Strings.  
The 'tEXt' chunk will encode this information.

---

## getText

public java.lang.String[] **getText**()  
Returns the text strings to be stored in uncompressed form with this image as an array of Strings.  
If the text strings have not previously been set, or have been unset, an `IllegalStateException` will be thrown.  
**Throws:**  
java.lang.IllegalStateException - if the text strings are not set.

---

## unsetText

public void **unsetText**()  
Suppresses the 'tEXt' chunk from being output.

---

## isTextSet

public boolean **isTextSet**()  
Returns true if a 'tEXt' chunk will be output.

---

## setModificationTime

public void **setModificationTime**(java.util.Date modificationTime)  
Sets the modification time, as a Date, to be stored with this image. The internal storage format will use UTC regardless of how the `modificationTime` parameter was created.  
The 'tIME' chunk will encode this information.

---

## getModificationTime

public java.util.Date **getModificationTime**()  
Returns the modification time to be stored with this image.  
If the bit depth has not previously been set, or has been unset, an `IllegalStateException` will be thrown.  
**Throws:**  
java.lang.IllegalStateException - if the bit depth is not set.

---

## unsetModificationTime

public void **unsetModificationTime**()  
Suppresses the 'tIME' chunk from being output.

---

## isModificationTimeSet

public boolean **isModificationTimeSet**()  
Returns true if a 'tIME' chunk will be output.

---

## **unsetTransparency**

public void **unsetTransparency**()  
Suppresses the 'tRNS' chunk from being output.

---

## **isTransparencySet**

public boolean **isTransparencySet**()  
Returns true if a 'tRNS' chunk will be output.

---

## **setCompressedText**

public void **setCompressedText**(java.lang.String[] text)  
Sets the text strings to be stored in compressed form with this image. The data is passed to this method as an array of Strings.  
The 'zTXt' chunk will encode this information.

---

## **getCompressedText**

public java.lang.String[] **getCompressedText**()  
Returns the text strings to be stored in compressed form with this image as an array of Strings.  
If the compressed text strings have not previously been set, or have been unset, an `IllegalStateException` will be thrown.  
**Throws:**  
java.lang.IllegalStateException - if the compressed text strings are not set.

---

## **unsetCompressedText**

public void **unsetCompressedText**()  
Suppresses the 'zTXt' chunk from being output.

---

## **isCompressedTextSet**

public boolean **isCompressedTextSet**()  
Returns true if a 'zTXt' chunk will be output.

---

## **addPrivateChunk**

public void **addPrivateChunk**(java.lang.String type,  
byte[] data)  
Adds a private chunk, in binary form, to the list of chunks to be stored with this image.  
**Parameters:**  
type - a 4-character String giving the chunk type name.  
data - an array of bytes containing the chunk data.

---

## **getNumPrivateChunks**

public int **getNumPrivateChunks**()  
Returns the number of private chunks to be written to the output file.

---

## **getPrivateChunkType**

public java.lang.String **getPrivateChunkType**(int index)  
Returns the type of the private chunk at a given index, as a 4-character String. The index must be smaller than the return value of `getNumPrivateChunks`.

---

## getPrivateChunkData

```
public byte[] getPrivateChunkData(int index)
```

Returns the data associated of the private chunk at a given index, as an array of bytes. The index must be smaller than the return value of `getNumPrivateChunks`.

---

## removeUnsafeToCopyPrivateChunks

```
public void removeUnsafeToCopyPrivateChunks()
```

Remove all private chunks associated with this parameter instance whose 'safe-to-copy' bit is not set. This may be advisable when transcoding PNG images.

---

## removeAllPrivateChunks

```
public void removeAllPrivateChunks()
```

Remove all private chunks associated with this parameter instance.

---

## abs

```
private static final int abs(int x)
```

An `abs()` function for use by the Paeth predictor.

---

## paethPredictor

```
public static final int paethPredictor(int a,  
                                       int b,  
                                       int c)
```

The Paeth predictor routine used in PNG encoding. This routine is included as a convenience to subclasses that override the `filterRow` method.

---

## filterRow

```
public int filterRow(byte[] currRow,  
                    byte[] prevRow,  
                    byte[][] scratchRows,  
                    int bytesPerRow,  
                    int bytesPerPixel)
```

Performs filtering on a row of an image. This method may be overridden in order to provide a custom algorithm for choosing the filter type for a given row.

The method is supplied with the current and previous rows of the image. For the first row of the image, or of an interlacing pass, the previous row array will be filled with zeros as required by the PNG specification.

The method is also supplied with five scratch arrays. These arrays may be used within the method for any purpose. At method exit, the array at the index given by the return value of the method should contain the filtered data. The return value will also be used as the filter type.

The default implementation of the method performs a trial encoding with each of the filter types, and computes the sum of absolute values of the differences between the raw bytes of the current row and the predicted values. The index of the filter producing the smallest result is returned.

As an example, to perform only 'sub' filtering, this method could be implemented (non-optimally) as follows:

```
for (int i = bytesPerPixel; i < bytesPerRow + bytesPerPixel; i++) {  
    int curr = currRow[i] & 0xff;  
    int left = currRow[i - bytesPerPixel] & 0xff;  
    scratchRow[PNG_FILTER_SUB][i] = (byte)(curr - left);  
}  
return PNG_FILTER_SUB;
```

### Parameters:

`currRow` - The current row as an array of bytes of length at least `bytesPerRow + bytesPerPixel`. The pixel data starts at index `bytesPerPixel`; the initial `bytesPerPixel` bytes are zero.

`prevRow` - The current row as an array of bytes. The pixel data starts at index `bytesPerPixel`; the initial `bytesPerPixel` bytes are zero.

`scratchRows` - An array of 5 byte arrays of length at least `bytesPerRow + bytesPerPixel`, useable to hold temporary results. The filtered row will be returned as one of the entries of this array. The returned filtered data should start at index `bytesPerPixel`; The initial `bytesPerPixel` bytes are not used.

`bytesPerRow` - The number of bytes in the image row. This value will always be greater than 0.

`bytesPerPixel` - The number of bytes representing a single pixel, rounded up to an integer. This is the 'bpp'

parameter described in the PNG specification.

**Returns:**

The filter type to be used. The entry of `scratchRows[ ]` at this index holds the filtered data.

---

**com.sun.media.jai.codec**

## **Class PNGSuggestedPaletteEntry**

java.lang.Object

|--com.sun.media.jai.codec.PNGSuggestedPaletteEntry

---

public class **PNGSuggestedPaletteEntry**

extends java.lang.Object

implements java.io.Serializable

A class representing the fields of a PNG suggested palette entry.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

### **Field Detail**

#### **name**

public java.lang.String **name**

The name of the entry.

---

#### **sampleDepth**

public int **sampleDepth**

The depth of the color samples.

---

#### **red**

public int **red**

The red color value of the entry.

---

#### **green**

public int **green**

The green color value of the entry.

---

#### **blue**

public int **blue**

The blue color value of the entry.

---

#### **alpha**

public int **alpha**

The alpha opacity value of the entry.

---

#### **frequency**

public int **frequency**

The probable frequency of the color in the image.

---

### **Constructor Detail**

#### **PNGSuggestedPaletteEntry**

public **PNGSuggestedPaletteEntry**()

---

**com.sun.media.jai.codec**  
**Class PNMEncodeParam**

```
java.lang.Object
|
+--com.sun.media.jai.codec.PNMEncodeParam
```

---

```
public class PNMEncodeParam
    extends java.lang.Object
    implements ImageEncodeParam
```

An instance of `ImageEncodeParam` for encoding images in the PNM format.

This class allows for the specification of whether to encode in the ASCII or raw variants of the PBM, PGM, and PPM formats. By default, raw encoding is used.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

### Field Detail

#### **raw**

```
private boolean raw
```

### Constructor Detail

#### **PNMEncodeParam**

```
public PNMEncodeParam()
    Constructs a PNMEncodeParam object with default values for parameters.
```

### Method Detail

#### **setRaw**

```
public void setRaw(boolean raw)
    Sets the representation to be used. If the raw parameter is true, raw encoding will be used; otherwise ASCII encoding will be used.
    Parameters:
        raw - true if raw format is to be used.
```

---

#### **getRaw**

```
public boolean getRaw()
    Returns the value of the raw parameter.
```

---

com.sun.media.jai.codec

## Class SectorStreamSegmentMapper

java.lang.Object

|--com.sun.media.jai.codec.SectorStreamSegmentMapper

---

class **SectorStreamSegmentMapper**

extends java.lang.Object

implements StreamSegmentMapper

An implementation of the StreamSegmentMapper interface for segments of equal length.

---

### Field Detail

#### segmentPositions

long[] **segmentPositions**

---

#### segmentLength

int **segmentLength**

---

#### totalLength

int **totalLength**

---

#### lastSegmentLength

int **lastSegmentLength**

---

### Constructor Detail

#### SectorStreamSegmentMapper

```
public SectorStreamSegmentMapper(long[] segmentPositions,  
                                int segmentLength,  
                                int totalLength)
```

---

### Method Detail

#### getStreamSegment

```
public StreamSegment getStreamSegment(long position,  
                                       int length)
```

**Specified by:**

getStreamSegment in interface StreamSegmentMapper

---

#### getStreamSegment

```
public void getStreamSegment(long position,  
                             int length,  
                             StreamSegment seg)
```

**Specified by:**

getStreamSegment in interface StreamSegmentMapper

---

## com.sun.media.jai.codec Class SeekableStream

```
java.lang.Object
|
+-- java.io.InputStream
|   |
|   +-- com.sun.media.jai.codec.SeekableStream
```

### Direct Known Subclasses:

ByteArraySeekableStream, FileCacheSeekableStream, FileSeekableStream, ForwardSeekableStream, MemoryCacheSeekableStream, SegmentedSeekableStream

---

public abstract class **SeekableStream**

extends java.io.InputStream

implements java.io.DataInput

An abstract subclass of java.io.InputStream that allows seeking within the input, similar to the RandomAccessFile class. Additionally, the DataInput interface is supported and extended to include support for little-endian representations of fundamental data types.

In addition to the familiar methods from InputStream, the methods getFilePointer(), seek(), are defined as in the RandomAccessFile class. The canSeekBackwards() method will return true if it is permissible to seek to a position earlier in the stream than the current value of getFilePointer(). Some subclasses of SeekableStream guarantee the ability to seek backwards while others may not offer this feature in the interest of providing greater efficiency for those users who do not require it.

The DataInput interface is supported as well. This included the skipBytes() and readFully() methods and a variety of read methods for various data types.

A number of concrete subclasses of SeekableStream are supplied in the com.sun.media.jai.codec package.

Three classes are provided for the purpose of adapting a standard InputStream to the SeekableStream interface. ForwardSeekableStream does not allow seeking backwards, but is inexpensive to use. FileCacheSeekableStream maintains a copy of all of the data read from the input in a temporary file; this file will be discarded automatically when the FileSeekableStream is finalized, or when the JVM exits normally. FileCacheSeekableStream is intended to be reasonably efficient apart from the unavoidable use of disk space. In circumstances where the creation of a temporary file is not possible, MemoryCacheSeekableStream may be used. MemoryCacheSeekableStream creates a potentially large in-memory buffer to store the stream data and so should be avoided when possible.

The FileSeekableStream class wraps a File or RandomAccessFile. It forwards requests to the real underlying file. It performs a limited amount of caching in order to avoid excessive I/O costs.

The SegmentedSeekableStream class performs a different sort of function. It creates a SeekableStream from another SeekableStream by selecting a series of portions or "segments". Each segment starts at a specified location within the source SeekableStream and extends for a specified number of bytes. The StreamSegmentMapper interface and StreamSegment class may be used to compute the segment positions dynamically.

A convenience method, wrapInputStream is provided to construct a suitable SeekableStream instance whose data is supplied by a given InputStream. The caller, by means of the canSeekBackwards parameter, determines whether support for seeking backwards is required.

<h2>Field Detail</h2>
-----------------------

### markPos

protected long **markPos**

Marked position

---

## ruileBuf

```
private byte[] ruileBuf
```

### Constructor Detail

## SeekableStream

```
public SeekableStream()
```

### Method Detail

## wrapInputStream

```
public static SeekableStream wrapInputStream(java.io.InputStream is,
                                             boolean canSeekBackwards)
```

Returns a `SeekableStream` that will read from a given `InputStream`, optionally including support for seeking backwards. This is a convenience method that avoids the need to instantiate specific subclasses of `SeekableStream` depending on the current security model.

**Parameters:**

`is` - An `InputStream`.

`canSeekBackwards` - true if the ability to seek backwards in the output is required.

**Returns:**

An instance of `SeekableStream`.

---

## read

```
public abstract int read()
    throws java.io.IOException
```

Reads the next byte of data from the input stream. The value byte is returned as an `int` in the range 0 to 255. If no byte is available because the end of the stream has been reached, the value `-1` is returned. This method blocks until input data is available, the end of the stream is detected, or an exception is thrown.

A subclass must provide an implementation of this method.

**Returns:**

the next byte of data, or `-1` if the end of the stream is reached.

**Throws:**

`java.io.IOException` - if an I/O error occurs.

**Overrides:**

`read` in class `java.io.InputStream`

---

## read

```
public abstract int read(byte[] b,
                        int off,
                        int len)
    throws java.io.IOException
```

Reads up to `len` bytes of data from the input stream into an array of bytes. An attempt is made to read as many as `len` bytes, but a smaller number may be read, possibly zero. The number of bytes actually read is returned as an integer.

This method blocks until input data is available, end of stream is detected, or an exception is thrown.

If `b` is null, a `NullPointerException` is thrown.

If `off` is negative, or `len` is negative, or `off+len` is greater than the length of the array `b`, then an `IndexOutOfBoundsException` is thrown.

If `len` is zero, then no bytes are read and 0 is returned; otherwise, there is an attempt to read at least one byte. If no byte is available because the stream is at end of stream, the value `-1` is returned; otherwise, at least one byte is read and stored into `b`.

The first byte read is stored into element `b[off]`, the next one into `b[off+1]`, and so on. The number of bytes read is, at most, equal to `len`. Let  $k$  be the number of bytes actually read; these bytes will be stored in elements `b[off]` through `b[off+k-1]`, leaving elements `b[off+k]` through `b[off+len-1]` unaffected.

In every case, elements `b[0]` through `b[off]` and elements `b[off+len]` through `b[b.length-1]` are unaffected.

If the first byte cannot be read for any reason other than end of stream, then an `IOException` is thrown. In particular, an `IOException` is thrown if the input stream has been closed.

A subclass must provide an implementation of this method.

**Parameters:**

b - the buffer into which the data is read.  
off - the start offset in array b at which the data is written.  
len - the maximum number of bytes to read.

**Returns:**

the total number of bytes read into the buffer, or -1 if there is no more data because the end of the stream has been reached.

**Throws:**

java.io.IOException - if an I/O error occurs.

**Overrides:**

read in class java.io.InputStream

---

**mark**

```
public void mark(int readLimit)
```

Marks the current file position for later return using the `reset()` method.

**Overrides:**

mark in class java.io.InputStream

---

**reset**

```
public void reset()  
    throws java.io.IOException
```

Returns the file position to its position at the time of the immediately previous call to the `mark()` method.

**Overrides:**

reset in class java.io.InputStream

---

**markSupported**

```
public boolean markSupported()
```

Returns true if marking is supported. Marking is automatically supported for `SeekableStream` subclasses that support seeking backwards. Subclasses that do not support seeking backwards but do support marking must override this method.

**Overrides:**

markSupported in class java.io.InputStream

---

**canSeekBackwards**

```
public boolean canSeekBackwards()
```

Returns true if this object supports calls to `seek(pos)` with an offset pos smaller than the current offset, as returned by `getFilePointer`.

---

**getFilePointer**

```
public abstract long getFilePointer()  
    throws java.io.IOException
```

Returns the current offset in this stream.

**Returns:**

the offset from the beginning of the stream, in bytes, at which the next read occurs.

**Throws:**

java.io.IOException - if an I/O error occurs.

---

**seek**

```
public abstract void seek(long pos)  
    throws java.io.IOException
```

Sets the offset, measured from the beginning of this stream, at which the next read occurs.

If `canSeekBackwards()` returns false, then setting pos to an offset smaller than the current value of `getFilePointer()` will have no effect.

**Parameters:**

pos - the offset position, measured in bytes from the beginning of the stream, at which to set the stream pointer.

**Throws:**

java.io.IOException - if pos is less than 0 or if an I/O error occurs.

---

## readFully

```
public final void readFully(byte[] b)
                        throws java.io.IOException
```

Reads `b.length` bytes from this stream into the byte array, starting at the current stream pointer. This method reads repeatedly from the stream until the requested number of bytes are read. This method blocks until the requested number of bytes are read, the end of the stream is detected, or an exception is thrown.

**Specified by:**

`readFully` in interface `java.io.DataInput`

**Parameters:**

`b` - the buffer into which the data is read.

**Throws:**

`java.io.EOFException` - if this stream reaches the end before reading all the bytes.

`java.io.IOException` - if an I/O error occurs.

---

## readFully

```
public final void readFully(byte[] b,
                           int off,
                           int len)
                        throws java.io.IOException
```

Reads exactly `len` bytes from this stream into the byte array, starting at the current stream pointer. This method reads repeatedly from the stream until the requested number of bytes are read. This method blocks until the requested number of bytes are read, the end of the stream is detected, or an exception is thrown.

**Specified by:**

`readFully` in interface `java.io.DataInput`

**Parameters:**

`b` - the buffer into which the data is read.

`off` - the start offset of the data.

`len` - the number of bytes to read.

**Throws:**

`java.io.EOFException` - if this stream reaches the end before reading all the bytes.

`java.io.IOException` - if an I/O error occurs.

---

## skipBytes

```
public int skipBytes(int n)
                throws java.io.IOException
```

Attempts to skip over `n` bytes of input discarding the skipped bytes.

This method may skip over some smaller number of bytes, possibly zero. This may result from any of a number of conditions; reaching end of stream before `n` bytes have been skipped is only one possibility. This method never throws an `EOFException`. The actual number of bytes skipped is returned. If `n` is negative, no bytes are skipped.

**Specified by:**

`skipBytes` in interface `java.io.DataInput`

**Parameters:**

`n` - the number of bytes to be skipped.

**Returns:**

the actual number of bytes skipped.

**Throws:**

`java.io.IOException` - if an I/O error occurs.

---

## readBoolean

```
public final boolean readBoolean()
                    throws java.io.IOException
```

Reads a boolean from this stream. This method reads a single byte from the stream, starting at the current stream pointer. A value of 0 represents `false`. Any other value represents `true`. This method blocks until the byte is read, the end of the stream is detected, or an exception is thrown.

**Specified by:**

`readBoolean` in interface `java.io.DataInput`

**Returns:**

the boolean value read.

**Throws:**

`java.io.EOFException` - if this stream has reached the end.

`java.io.IOException` - if an I/O error occurs.

---

## readByte

```
public final byte readByte()  
                throws java.io.IOException
```

Reads a signed eight-bit value from this stream. This method reads a byte from the stream, starting from the current stream pointer. If the byte read is *b*, where  $0 \leq b \leq 255$ , then the result is:

`(byte)(b)`

This method blocks until the byte is read, the end of the stream is detected, or an exception is thrown.

**Specified by:**

readByte in interface java.io.DataInput

**Returns:**

the next byte of this stream as a signed eight-bit byte.

**Throws:**

java.io.EOFException - if this stream has reached the end.

java.io.IOException - if an I/O error occurs.

---

## readUnsignedByte

```
public final int readUnsignedByte()  
                throws java.io.IOException
```

Reads an unsigned eight-bit number from this stream. This method reads a byte from this stream, starting at the current stream pointer, and returns that byte.

This method blocks until the byte is read, the end of the stream is detected, or an exception is thrown.

**Specified by:**

readUnsignedByte in interface java.io.DataInput

**Returns:**

the next byte of this stream, interpreted as an unsigned eight-bit number.

**Throws:**

java.io.EOFException - if this stream has reached the end.

java.io.IOException - if an I/O error occurs.

---

## readShort

```
public final short readShort()  
                throws java.io.IOException
```

Reads a signed 16-bit number from this stream. The method reads two bytes from this stream, starting at the current stream pointer. If the two bytes read, in order, are *b1* and *b2*, where each of the two values is between 0 and 255, inclusive, then the result is equal to:

`(short)((b1 << 8) | b2)`

This method blocks until the two bytes are read, the end of the stream is detected, or an exception is thrown.

**Specified by:**

readShort in interface java.io.DataInput

**Returns:**

the next two bytes of this stream, interpreted as a signed 16-bit number.

**Throws:**

java.io.EOFException - if this stream reaches the end before reading two bytes.

java.io.IOException - if an I/O error occurs.

---

## readShortLE

```
public final short readShortLE()  
                throws java.io.IOException
```

Reads a signed 16-bit number from this stream in little-endian order. The method reads two bytes from this stream, starting at the current stream pointer. If the two bytes read, in order, are *b1* and *b2*, where each of the two values is between 0 and 255, inclusive, then the result is equal to:

`(short)((b2 << 8) | b1)`

This method blocks until the two bytes are read, the end of the stream is detected, or an exception is thrown.

**Returns:**

the next two bytes of this stream, interpreted as a signed 16-bit number.

**Throws:**

java.io.EOFException - if this stream reaches the end before reading two bytes.

java.io.IOException - if an I/O error occurs.

---

## readUnsignedShort

```
public final int readUnsignedShort()  
                  throws java.io.IOException
```

Reads an unsigned 16-bit number from this stream. This method reads two bytes from the stream, starting at the current stream pointer. If the bytes read, in order, are b1 and b2, where  $0 \leq b1, b2 \leq 255$ , then the result is equal to:

$$(b1 \ll 8) \mid b2$$

This method blocks until the two bytes are read, the end of the stream is detected, or an exception is thrown.

**Specified by:**

readUnsignedShort in interface java.io.DataInput

**Returns:**

the next two bytes of this stream, interpreted as an unsigned 16-bit integer.

**Throws:**

java.io.EOFException - if this stream reaches the end before reading two bytes.

java.io.IOException - if an I/O error occurs.

---

## readUnsignedShortLE

```
public final int readUnsignedShortLE()  
                  throws java.io.IOException
```

Reads an unsigned 16-bit number from this stream in little-endian order. This method reads two bytes from the stream, starting at the current stream pointer. If the bytes read, in order, are b1 and b2, where  $0 \leq b1, b2 \leq 255$ , then the result is equal to:

$$(b2 \ll 8) \mid b1$$

This method blocks until the two bytes are read, the end of the stream is detected, or an exception is thrown.

**Returns:**

the next two bytes of this stream, interpreted as an unsigned 16-bit integer.

**Throws:**

java.io.EOFException - if this stream reaches the end before reading two bytes.

java.io.IOException - if an I/O error occurs.

---

## readChar

```
public final char readChar()  
                  throws java.io.IOException
```

Reads a Unicode character from this stream. This method reads two bytes from the stream, starting at the current stream pointer. If the bytes read, in order, are b1 and b2, where  $0 \leq b1, b2 \leq 255$ , then the result is equal to:

$$(\text{char})((b1 \ll 8) \mid b2)$$

This method blocks until the two bytes are read, the end of the stream is detected, or an exception is thrown.

**Specified by:**

readChar in interface java.io.DataInput

**Returns:**

the next two bytes of this stream as a Unicode character.

**Throws:**

java.io.EOFException - if this stream reaches the end before reading two bytes.

java.io.IOException - if an I/O error occurs.

---

## readCharLE

```
public final char readCharLE()  
                  throws java.io.IOException
```

Reads a Unicode character from this stream in little-endian order. This method reads two bytes from the stream, starting at the current stream pointer. If the bytes read, in order, are `b1` and `b2`, where  $0 \leq b1, b2 \leq 255$ , then the result is equal to:

$$(\text{char})((b2 \ll 8) \mid b1)$$

This method blocks until the two bytes are read, the end of the stream is detected, or an exception is thrown.

**Returns:**

the next two bytes of this stream as a Unicode character.

**Throws:**

`java.io.EOFException` - if this stream reaches the end before reading two bytes.

`java.io.IOException` - if an I/O error occurs.

---

## readInt

```
public final int readInt()
    throws java.io.IOException
```

Reads a signed 32-bit integer from this stream. This method reads 4 bytes from the stream, starting at the current stream pointer. If the bytes read, in order, are `b1`, `b2`, `b3`, and `b4`, where  $0 \leq b1, b2, b3, b4 \leq 255$ , then the result is equal to:

$$(b1 \ll 24) \mid (b2 \ll 16) + (b3 \ll 8) + b4$$

This method blocks until the four bytes are read, the end of the stream is detected, or an exception is thrown.

**Specified by:**

`readInt` in interface `java.io.DataInput`

**Returns:**

the next four bytes of this stream, interpreted as an `int`.

**Throws:**

`java.io.EOFException` - if this stream reaches the end before reading four bytes.

`java.io.IOException` - if an I/O error occurs.

---

## readIntLE

```
public final int readIntLE()
    throws java.io.IOException
```

Reads a signed 32-bit integer from this stream in little-endian order. This method reads 4 bytes from the stream, starting at the current stream pointer. If the bytes read, in order, are `b1`, `b2`, `b3`, and `b4`, where  $0 \leq b1, b2, b3, b4 \leq 255$ , then the result is equal to:

$$(b4 \ll 24) \mid (b3 \ll 16) + (b2 \ll 8) + b1$$

This method blocks until the four bytes are read, the end of the stream is detected, or an exception is thrown.

**Returns:**

the next four bytes of this stream, interpreted as an `int`.

**Throws:**

`java.io.EOFException` - if this stream reaches the end before reading four bytes.

`java.io.IOException` - if an I/O error occurs.

---

## readUnsignedInt

```
public final long readUnsignedInt()
    throws java.io.IOException
```

Reads an unsigned 32-bit integer from this stream. This method reads 4 bytes from the stream, starting at the current stream pointer. If the bytes read, in order, are `b1`, `b2`, `b3`, and `b4`, where  $0 \leq b1, b2, b3, b4 \leq 255$ , then the result is equal to:

$$(b1 \ll 24) \mid (b2 \ll 16) + (b3 \ll 8) + b4$$

This method blocks until the four bytes are read, the end of the stream is detected, or an exception is thrown.

**Returns:**

the next four bytes of this stream, interpreted as a `long`.

**Throws:**

`java.io.EOFException` - if this stream reaches the end before reading four bytes.

`java.io.IOException` - if an I/O error occurs.

---

## readUnsignedIntLE

```
public final long readUnsignedIntLE()  
    throws java.io.IOException
```

Reads an unsigned 32-bit integer from this stream in little-endian order. This method reads 4 bytes from the stream, starting at the current stream pointer. If the bytes read, in order, are b1, b2, b3, and b4, where  $0 \leq b1, b2, b3, b4 \leq 255$ , then the result is equal to:

$$(b4 \ll 24) \mid (b3 \ll 16) + (b2 \ll 8) + b1$$

This method blocks until the four bytes are read, the end of the stream is detected, or an exception is thrown.

**Returns:**

the next four bytes of this stream, interpreted as a long.

**Throws:**

java.io.EOFException - if this stream reaches the end before reading four bytes.

java.io.IOException - if an I/O error occurs.

---

## readLong

```
public final long readLong()  
    throws java.io.IOException
```

Reads a signed 64-bit integer from this stream. This method reads eight bytes from the stream, starting at the current stream pointer. If the bytes read, in order, are b1, b2, b3, b4, b5, b6, b7, and b8, where:

$$0 \leq b1, b2, b3, b4, b5, b6, b7, b8 \leq 255,$$

then the result is equal to:

$$\begin{aligned} & ((\text{long})b1 \ll 56) + ((\text{long})b2 \ll 48) \\ & + ((\text{long})b3 \ll 40) + ((\text{long})b4 \ll 32) \\ & + ((\text{long})b5 \ll 24) + ((\text{long})b6 \ll 16) \\ & + ((\text{long})b7 \ll 8) + b8 \end{aligned}$$

This method blocks until the eight bytes are read, the end of the stream is detected, or an exception is thrown.

**Specified by:**

readLong in interface java.io.DataInput

**Returns:**

the next eight bytes of this stream, interpreted as a long.

**Throws:**

java.io.EOFException - if this stream reaches the end before reading eight bytes.

java.io.IOException - if an I/O error occurs.

---

## readLongLE

```
public final long readLongLE()  
    throws java.io.IOException
```

Reads a signed 64-bit integer from this stream in little-endian order. This method reads eight bytes from the stream, starting at the current stream pointer. If the bytes read, in order, are b1, b2, b3, b4, b5, b6, b7, and b8, where:

$$0 \leq b1, b2, b3, b4, b5, b6, b7, b8 \leq 255,$$

then the result is equal to:

$$\begin{aligned} & ((\text{long})b1 \ll 56) + ((\text{long})b2 \ll 48) \\ & + ((\text{long})b3 \ll 40) + ((\text{long})b4 \ll 32) \\ & + ((\text{long})b5 \ll 24) + ((\text{long})b6 \ll 16) \\ & + ((\text{long})b7 \ll 8) + b8 \end{aligned}$$

This method blocks until the eight bytes are read, the end of the stream is detected, or an exception is thrown.

**Returns:**

the next eight bytes of this stream, interpreted as a long.

**Throws:**

java.io.EOFException - if this stream reaches the end before reading eight bytes.

java.io.IOException - if an I/O error occurs.

---

## readFloat

```
public final float readFloat()  
    throws java.io.IOException
```

Reads a float from this stream. This method reads an int value, starting at the current stream pointer, as if by the readInt method and then converts that int to a float using the intBitsToFloat method in class Float.

This method blocks until the four bytes are read, the end of the stream is detected, or an exception is thrown.

**Specified by:**

readFloat in interface java.io.DataInput

**Returns:**

the next four bytes of this stream, interpreted as a float.

**Throws:**

java.io.EOFException - if this stream reaches the end before reading four bytes.

java.io.IOException - if an I/O error occurs.

---

## readFloatLE

```
public final float readFloatLE()  
    throws java.io.IOException
```

Reads a float from this stream in little-endian order. This method reads an int value, starting at the current stream pointer, as if by the readInt method and then converts that int to a float using the intBitsToFloat method in class Float.

This method blocks until the four bytes are read, the end of the stream is detected, or an exception is thrown.

**Returns:**

the next four bytes of this stream, interpreted as a float.

**Throws:**

java.io.EOFException - if this stream reaches the end before reading four bytes.

java.io.IOException - if an I/O error occurs.

---

## readDouble

```
public final double readDouble()  
    throws java.io.IOException
```

Reads a double from this stream. This method reads a long value, starting at the current stream pointer, as if by the readLong method and then converts that long to a double using the longBitsToDouble method in class Double.

This method blocks until the eight bytes are read, the end of the stream is detected, or an exception is thrown.

**Specified by:**

readDouble in interface java.io.DataInput

**Returns:**

the next eight bytes of this stream, interpreted as a double.

**Throws:**

java.io.EOFException - if this stream reaches the end before reading eight bytes.

java.io.IOException - if an I/O error occurs.

---

## readDoubleLE

```
public final double readDoubleLE()  
    throws java.io.IOException
```

Reads a double from this stream in little-endian order. This method reads a long value, starting at the current stream pointer, as if by the readLong method and then converts that long to a double using the longBitsToDouble method in class Double.

This method blocks until the eight bytes are read, the end of the stream is detected, or an exception is thrown.

**Returns:**

the next eight bytes of this stream, interpreted as a double.

**Throws:**

java.io.EOFException - if this stream reaches the end before reading eight bytes.

java.io.IOException - if an I/O error occurs.

---

## readLine

```
public final java.lang.String readLine()  
    throws java.io.IOException
```

Reads the next line of text from this stream. This method successively reads bytes from the stream, starting at the current stream pointer, until it reaches a line terminator or the end of the stream. Each byte is converted into a character by taking the byte's value for the lower eight bits of the character and setting the high eight bits of the character to zero. This method does not, therefore, support the full Unicode character set.

A line of text is terminated by a carriage-return character ( ' \r ' ), a newline character ( ' \n ' ), a carriage-return character immediately followed by a newline character, or the end of the stream. Line-terminating characters are discarded and are not included as part of the string returned.

This method blocks until a newline character is read, a carriage return and the byte following it are read (to see if it is a newline), the end of the stream is reached, or an exception is thrown.

**Specified by:**

readLine in interface java.io.DataInput

**Returns:**

the next line of text from this stream, or null if end of stream is encountered before even one byte is read.

**Throws:**

java.io.IOException - if an I/O error occurs.

---

## readUTF

```
public final java.lang.String readUTF()  
    throws java.io.IOException
```

Reads in a string from this stream. The string has been encoded using a modified UTF-8 format.

The first two bytes are read, starting from the current stream pointer, as if by readUnsignedShort. This value gives the number of following bytes that are in the encoded string, not the length of the resulting string. The following bytes are then interpreted as bytes encoding characters in the UTF-8 format and are converted into characters.

This method blocks until all the bytes are read, the end of the stream is detected, or an exception is thrown.

**Specified by:**

readUTF in interface java.io.DataInput

**Returns:**

a Unicode string.

**Throws:**

java.io.EOFException - if this stream reaches the end before reading all the bytes.

java.io.IOException - if an I/O error occurs.

UTFDataFormatException - if the bytes do not represent valid UTF-8 encoding of a Unicode string.

---

## finalize

```
protected void finalize()  
    throws java.lang.Throwable
```

Releases any system resources associated with this stream by calling the close( ) method.

**Overrides:**

finalize in class java.lang.Object

---

**com.sun.media.jai.codec**

## **Class SegmentedSeekableStream**

```
java.lang.Object
|
+--java.io.InputStream
|   |
|   +--com.sun.media.jai.codec.SeekableStream
|       |
|       +--com.sun.media.jai.codec.SegmentedSeekableStream
```

---

public class **SegmentedSeekableStream**  
extends `SeekableStream`

A `SegmentedSeekableStream` provides a view of a subset of another `SeekableStream` consisting of a series of segments with given starting positions in the source stream and lengths. The resulting stream behaves like an ordinary `SeekableStream`. For example, given a `SeekableStream` containing data in a format consisting of a number of sub-streams stored in non-contiguous sectors indexed by a directory, it is possible to construct a set of `SegmentedSeekableStreams`, one for each sub-stream, that each provide a view of the sectors comprising a particular stream by providing the positions and lengths of the stream's sectors as indicated by the directory. The complex multi-stream structure of the original stream may be ignored by users of the `SegmentedSeekableStream`, who see a separate `SeekableStream` for each sub-stream and do not need to understand the directory structure at all.

For further efficiency, a directory structure such as in the example described above need not be fully parsed in order to build a `SegmentedSeekableStream`. Instead, the `StreamSegmentMapper` interface allows the association between a desired region of the output and an input segment to be provided dynamically. This mapping might be computed by reading from a directory in piecemeal fashion in order to avoid consuming memory resources.

It is the responsibility of the user of this class to determine whether backwards seeking should be enabled. If the source stream supports only forward seeking, backwards seeking must be disabled and the `StreamSegmentMapper` must be monotone; that is, forward motion in the destination must always result in forward motion within the source. If the source stream supports backwards seeking, there are no restrictions on the `StreamSegmentMapper` and backwards seeking may always be enabled for the `SegmentedSeekableStream`.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

### **Field Detail**

#### **stream**

private `SeekableStream` **stream**

---

#### **mapper**

private `StreamSegmentMapper` **mapper**

---

#### **pointer**

private long **pointer**

---

#### **canSeekBackwards**

private boolean **canSeekBackwards**

---

#### **streamSegment**

private `StreamSegment` **streamSegment**

---

### **Constructor Detail**

## SegmentedSeekableStream

```
public SegmentedSeekableStream(SeekableStream stream,  
                               StreamSegmentMapper mapper,  
                               boolean canSeekBackwards)
```

Constructs a `SegmentedSeekableStream` given a `SeekableStream` as input, an instance of `StreamSegmentMapper`, and a boolean indicating whether the output `SegmentedSeekableStream` should support seeking backwards. If `canSeekBackwards` is true, the source stream must itself support seeking backwards.

**Parameters:**

`stream` - A source `SeekableStream`  
`mapper` - An instance of the `StreamSegmentMapper` interface.  
`canSeekBackwards` - true if the ability to seek backwards is desired.

---

## SegmentedSeekableStream

```
public SegmentedSeekableStream(SeekableStream stream,  
                               long[] segmentPositions,  
                               int[] segmentLengths,  
                               boolean canSeekBackwards)
```

Constructs a `SegmentedSeekableStream` given a `SeekableStream` as input, a list of the starting positions and lengths of the segments of the source stream, and a boolean indicating whether the output `SegmentedSeekableStream` should support seeking backwards. If `canSeekBackwards` is true, the source stream must itself support seeking backwards.

**Parameters:**

`stream` - A source `SeekableStream`  
`segmentPositions` - An array of longs giving the starting positions of the segments in the source stream.  
`segmentLengths` - An array of ints giving the lengths of segments in the source stream.  
`canSeekBackwards` - true if the ability to seek backwards is desired.

---

## SegmentedSeekableStream

```
public SegmentedSeekableStream(SeekableStream stream,  
                               long[] segmentPositions,  
                               int segmentLength,  
                               int totalLength,  
                               boolean canSeekBackwards)
```

Constructs a `SegmentedSeekableStream` given a `SeekableStream` as input, a list of the starting positions of the segments of the source stream, the common length of each segment, the total length of the segments and a boolean indicating whether the output `SegmentedSeekableStream` should support seeking backwards. If `canSeekBackwards` is true, the source stream must itself support seeking backwards.

This constructor is useful for selecting substreams of sector-oriented file formats in which each segment of the substream (except possibly the final segment) occupies a fixed-length sector.

**Parameters:**

`stream` - A source `SeekableStream`  
`segmentPositions` - An array of longs giving the starting positions of the segments in the source stream.  
`segmentLength` - The common length of each segment.  
`totalLength` - The total length of the source segments.  
`canSeekBackwards` - true if the ability to seek backwards is desired.

---

## Method Detail

### getFilePointer

```
public long getFilePointer()
```

Returns the current offset in this stream.

**Returns:**

the offset from the beginning of the stream, in bytes, at which the next read occurs.

**Overrides:**

`getFilePointer` in class `SeekableStream`

---

## canSeekBackwards

```
public boolean canSeekBackwards()
```

Returns true if seeking backwards is supported. Support is determined by the value of the `canSeekBackwards` parameter at construction time.

**Overrides:**

`canSeekBackwards` in class `SeekableStream`

---

## seek

```
public void seek(long pos)
    throws java.io.IOException
```

Sets the offset, measured from the beginning of this stream, at which the next read occurs.

If `canSeekBackwards()` returns false, then setting `pos` to an offset smaller than the current value of `getFilePointer()` will have no effect.

**Parameters:**

`pos` - the offset position, measured in bytes from the beginning of the stream, at which to set the stream pointer.

**Throws:**

`java.io.IOException` - if `pos` is less than 0 or if an I/O error occurs.

**Overrides:**

`seek` in class `SeekableStream`

---

## read

```
public int read()
    throws java.io.IOException
```

Reads the next byte of data from the input stream. The value byte is returned as an `int` in the range 0 to 255. If no byte is available because the end of the stream has been reached, the value `-1` is returned. This method blocks until input data is available, the end of the stream is detected, or an exception is thrown.

**Returns:**

the next byte of data, or `-1` if the end of the stream is reached.

**Throws:**

`java.io.IOException` - if an I/O error occurs.

**Overrides:**

`read` in class `SeekableStream`

---

## read

```
public int read(byte[] b,
               int off,
               int len)
    throws java.io.IOException
```

Reads up to `len` bytes of data from the input stream into an array of bytes. An attempt is made to read as many as `len` bytes, but a smaller number may be read, possibly zero. The number of bytes actually read is returned as an integer.

This method blocks until input data is available, end of stream is detected, or an exception is thrown.

If `b` is null, a `NullPointerException` is thrown.

If `off` is negative, or `len` is negative, or `off+len` is greater than the length of the array `b`, then an `IndexOutOfBoundsException` is thrown.

If `len` is zero, then no bytes are read and 0 is returned; otherwise, there is an attempt to read at least one byte. If no byte is available because the stream is at end of stream, the value `-1` is returned; otherwise, at least one byte is read and stored into `b`.

The first byte read is stored into element `b[off]`, the next one into `b[off+1]`, and so on. The number of bytes read is, at most, equal to `len`. Let `k` be the number of bytes actually read; these bytes will be stored in elements `b[off]` through `b[off+k-1]`, leaving elements `b[off+k]` through `b[off+len-1]` unaffected.

In every case, elements `b[0]` through `b[off]` and elements `b[off+len]` through `b[b.length-1]` are unaffected.

If the first byte cannot be read for any reason other than end of stream, then an `IOException` is thrown. In particular, an `IOException` is thrown if the input stream has been closed.

**Parameters:**

`b` - the buffer into which the data is read.

`off` - the start offset in array `b` at which the data is written.

`len` - the maximum number of bytes to read.

**Returns:**

the total number of bytes read into the buffer, or `-1` if there is no more data because the end of the stream has been reached.

**Throws:**

java.io.IOException - if an I/O error occurs.

**Overrides:**

read in class SeekableStream

---

**com.sun.media.jai.codec**  
**Class StreamSegment**

java.lang.Object  
|  
+--com.sun.media.jai.codec.StreamSegment

---

public class **StreamSegment**  
extends java.lang.Object

A utility class representing a segment within a stream as a long starting position and an int length.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

## Field Detail

### startPos

private long **startPos**

---

### segmentLength

private int **segmentLength**

---

## Constructor Detail

### StreamSegment

public **StreamSegment**()

Constructs a **StreamSegment**. The starting position and length are set to 0.

---

### StreamSegment

public **StreamSegment**(long startPos,  
int segmentLength)

Constructs a **StreamSegment** with a given starting position and length.

---

## Method Detail

### getStartPos

public final long **getStartPos**()

Returns the starting position of the segment.

---

### setStartPos

public final void **setStartPos**(long startPos)

Sets the starting position of the segment.

---

### getSegmentLength

public final int **getSegmentLength**()

Returns the length of the segment.

---

### setSegmentLength

public final void **setSegmentLength**(int segmentLength)

Sets the length of the segment.

com.sun.media.jai.codec

## Interface StreamSegmentMapper

All Known Implementing Classes:

SectorStreamSegmentMapper, StreamSegmentMapperImpl

---

public abstract interface **StreamSegmentMapper**

An interface for use with the `SegmentedSeekableStream` class. An instance of the `StreamSegmentMapper` interface provides the location and length of a segment of a source `SeekableStream` corresponding to the initial portion of a desired segment of the output stream.

As an example, consider a mapping between a source `SeekableStream` `src` and a `SegmentedSeekableStream` `dst` comprising bytes 100-149 and 200-249 of the source stream. The `dst` stream has a reference to an instance `mapper` of `StreamSegmentMapper`.

A call to `dst.seek(0); dst.read(buf, 0, 10)` will result in a call to `mapper.getStreamSegment(0, 10)`, returning a new `StreamSegment` with a starting position of 100 and a length of 10 (or less). This indicates that in order to read bytes 0-9 of the segmented stream, bytes 100-109 of the source stream should be read.

A call to `dst.seek(10); int nbytes = dst.read(buf, 0, 100)` is somewhat more complex, since it will require data from both segments of `src`. The method `mapper.getStreamSegment(10, 100)` will be called. This method will return a new `StreamSegment` with a starting position of 110 and a length of 40 (or less). The length is limited to 40 since a longer value would result in a read past the end of the first segment. The read will stop after the first 40 bytes and an additional read or reads will be required to obtain the data contained in the second segment.

**This interface is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

### Method Detail

#### getStreamSegment

```
public StreamSegment getStreamSegment(long pos,  
                                       int length)
```

Returns a `StreamSegment` object indicating the location of the initial portion of a desired segment in the source stream. The length of the returned `StreamSegment` may be smaller than the desired length.

**Parameters:**

`pos` - The desired starting position in the `SegmentedSeekableStream`, as a long.  
`length` - The desired segment length.

---

#### getStreamSegment

```
public void getStreamSegment(long pos,  
                             int length,  
                             StreamSegment seg)
```

Sets the values of a `StreamSegment` object indicating the location of the initial portion of a desired segment in the source stream. The length of the returned `StreamSegment` may be smaller than the desired length.

**Parameters:**

`pos` - The desired starting position in the `SegmentedSeekableStream`, as a long.  
`length` - The desired segment length.  
`seg` - A `StreamSegment` object to be overwritten.

---

**com.sun.media.jai.codec**

## **Class StreamSegmentMapperImpl**

java.lang.Object

|--com.sun.media.jai.codec.StreamSegmentMapperImpl

---

class **StreamSegmentMapperImpl**

extends java.lang.Object

implements StreamSegmentMapper

An implementation of the StreamSegmentMapper interface that requires an explicit list of the starting locations and lengths of the source segments.

---

### **Field Detail**

#### **segmentPositions**

private long[] **segmentPositions**

---

#### **segmentLengths**

private int[] **segmentLengths**

---

### **Constructor Detail**

#### **StreamSegmentMapperImpl**

```
public StreamSegmentMapperImpl(long[] segmentPositions,  
                                int[] segmentLengths)
```

---

### **Method Detail**

#### **getStreamSegment**

```
public StreamSegment getStreamSegment(long position,  
                                         int length)
```

**Specified by:**

getStreamSegment in interface StreamSegmentMapper

---

#### **getStreamSegment**

```
public void getStreamSegment(long position,  
                              int length,  
                              StreamSegment seg)
```

**Specified by:**

getStreamSegment in interface StreamSegmentMapper

---

**com.sun.media.jai.codec**  
**Class TIFFDecodeParam**

```
java.lang.Object
|
+--com.sun.media.jai.codec.TIFFDecodeParam
```

---

```
public class TIFFDecodeParam
    extends java.lang.Object
    implements ImageDecodeParam
```

An instance of ImageDecodeParam for decoding images in the TIFF format.

To determine the number of images present in a TIFF file, use the `getNumPages()` method on the ImageDecoder object that will be used to perform the decoding. The desired page number may be passed as an argument to the `ImageDecoder.decodeAsRaster()` or `decodeAsRenderedImage()` methods.

For TIFF Palette color images, the colorMap always has entries of short data type, the color Black being represented by 0,0,0 and White by 65536,65536,65536. In order to display these images, the default behavior is to dither the short values down to 8 bits. The dithering is done by calling the `decode16BitsTo8Bits` method for each short value that needs to be dithered. The method has the following implementation: `byte b; short s; s = s & 0xffff; b = (byte)((s >> 8) & 0xff);` If a different algorithm is to be used for the dithering, this class should be subclassed and an appropriate implementation should be provided for the `decode16BitsTo8Bits` method in the subclass.

If the palette contains image data that is signed short, as specified by the SampleFormat tag, the dithering is done by calling `decodeSigned16BitsTo8Bits` instead. The method has the following implementation: `byte b; short s; b = (byte)((s + Short.MIN_VALUE) >> 8);` In order to use a different algorithm for the dithering, this class should be subclassed and the method overridden.

If it is desired that the Palette be decoded such that the output image is of short data type and no dithering is performed, the `setDecodePaletteAsShorts` method should be used.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

**See Also:**

TIFFDirectory

---

## Field Detail

### decodePaletteAsShorts

```
private boolean decodePaletteAsShorts
```

## Constructor Detail

### TIFFDecodeParam

```
public TIFFDecodeParam()
```

Constructs a default instance of TIFFDecodeParam.

## Method Detail

### setDecodePaletteAsShorts

```
public void setDecodePaletteAsShorts(boolean decodePaletteAsShorts)
```

If set, the entries in the palette will be decoded as shorts and no short to byte lookup will be applied to them.

---

### getDecodePaletteAsShorts

```
public boolean getDecodePaletteAsShorts()
```

Returns true if palette entries will be decoded as shorts, resulting in an output image with short datatype.

---

## **decode16BitsTo8Bits**

```
public byte decode16BitsTo8Bits(int s)
```

Returns an unsigned 8 bit value computed by dithering the unsigned 16 bit value. Note that the TIFF specified short datatype is an unsigned value, while Java's `short` datatype is a signed value. Therefore the Java `short` datatype cannot be used to store the TIFF specified short value. A Java `int` is used as input instead to this method. The method deals correctly only with 16 bit unsigned values.

---

## **decodeSigned16BitsTo8Bits**

```
public byte decodeSigned16BitsTo8Bits(short s)
```

Returns an unsigned 8 bit value computed by dithering the signed 16 bit value. This method deals correctly only with values in the 16 bit signed range.

---

## com.sun.media.jai.codec Class TIFFDirectory

```
java.lang.Object
|
+--com.sun.media.jai.codec.TIFFDirectory
```

---

public class **TIFFDirectory**  
extends java.lang.Object

A class representing an Image File Directory (IFD) from a TIFF 6.0 stream. The TIFF file format is described in more detail in the comments for the TIFFDescriptor class.

A TIFF IFD consists of a set of TIFFField tags. Methods are provided to query the set of tags and to obtain the raw field array. In addition, convenience methods are provided for acquiring the values of tags that contain a single value that fits into a byte, int, long, float, or double.

Every TIFF file is made up of one or more public IFDs that are joined in a linked list, rooted in the file header. A file may also contain so-called private IFDs that are referenced from tag data and do not appear in the main list.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

TIFFDescriptor, TIFFField

---

### Field Detail

#### stream

SeekableStream **stream**

The stream being read.

---

#### isBigEndian

boolean **isBigEndian**

A boolean storing the endianness of the stream.

---

#### numEntries

int **numEntries**

The number of entries in the IFD.

---

#### fields

TIFFField[] **fields**

An array of TIFFFields.

---

#### fieldIndex

java.util.Hashtable **fieldIndex**

A Hashtable indexing the fields by tag number.

---

#### sizeOfType

private static final int[] **sizeOfType**

---

### Constructor Detail

## TIFFDirectory

**TIFFDirectory()**

The default constructor.

---

## TIFFDirectory

```
public TIFFDirectory(SeekableStream stream,
                     int directory)
    throws java.io.IOException
```

Constructs a TIFFDirectory from a SeekableStream. The directory parameter specifies which directory to read from the linked list present in the stream; directory 0 is normally read but it is possible to store multiple images in a single TIFF file by maintaining multiple directories.

**Parameters:**

stream - a SeekableStream to read from.  
directory - the index of the directory to read.

---

## TIFFDirectory

```
public TIFFDirectory(SeekableStream stream,
                     long ifd_offset)
    throws java.io.IOException
```

Constructs a TIFFDirectory by reading a SeekableStream. The ifd\_offset parameter specifies the stream offset from which to begin reading; this mechanism is sometimes used to store private IFDs within a TIFF file that are not part of the normal sequence of IFDs.

**Parameters:**

stream - a SeekableStream to read from.  
ifd\_offset - the long byte offset of the directory.

---

## Method Detail

### isValidEndianTag

```
private static boolean isValidEndianTag(int endian)
```

---

### initialize

```
private void initialize()
    throws java.io.IOException
```

---

### getNumEntries

```
public int getNumEntries()
    Returns the number of directory entries.
```

---

### getField

```
public TIFFField getField(int tag)
    Returns the value of a given tag as a TIFFField, or null if the tag is not present.
```

---

### isTagPresent

```
public boolean isTagPresent(int tag)
    Returns true if a tag appears in the directory.
```

---

### getTags

```
public int[] getTags()
    Returns an ordered array of ints indicating the tag values.
```

---

## getFields

```
public TIFFField[] getFields()
```

Returns an array of TIFFFields containing all the fields in this directory.

---

## getFieldAsByte

```
public byte getFieldAsByte(int tag,  
                           int index)
```

Returns the value of a particular index of a given tag as a byte. The caller is responsible for ensuring that the tag is present and has type TIFFField.TIFF\_SBYTE, TIFF\_BYTE, or TIFF\_UNDEFINED.

---

## getFieldAsByte

```
public byte getFieldAsByte(int tag)
```

Returns the value of index 0 of a given tag as a byte. The caller is responsible for ensuring that the tag is present and has type TIFFField.TIFF\_SBYTE, TIFF\_BYTE, or TIFF\_UNDEFINED.

---

## getFieldAsLong

```
public long getFieldAsLong(int tag,  
                           int index)
```

Returns the value of a particular index of a given tag as a long. The caller is responsible for ensuring that the tag is present and has type TIFF\_BYTE, TIFF\_SBYTE, TIFF\_UNDEFINED, TIFF\_SHORT, TIFF\_SSHORT, TIFF\_SLONG or TIFF\_LONG.

---

## getFieldAsLong

```
public long getFieldAsLong(int tag)
```

Returns the value of index 0 of a given tag as a long. The caller is responsible for ensuring that the tag is present and has type TIFF\_BYTE, TIFF\_SBYTE, TIFF\_UNDEFINED, TIFF\_SHORT, TIFF\_SSHORT, TIFF\_SLONG or TIFF\_LONG.

---

## getFieldAsFloat

```
public float getFieldAsFloat(int tag,  
                             int index)
```

Returns the value of a particular index of a given tag as a float. The caller is responsible for ensuring that the tag is present and has numeric type (all but TIFF\_UNDEFINED and TIFF\_ASCII).

---

## getFieldAsFloat

```
public float getFieldAsFloat(int tag)
```

Returns the value of index 0 of a given tag as a float. The caller is responsible for ensuring that the tag is present and has numeric type (all but TIFF\_UNDEFINED and TIFF\_ASCII).

---

## getFieldAsDouble

```
public double getFieldAsDouble(int tag,  
                               int index)
```

Returns the value of a particular index of a given tag as a double. The caller is responsible for ensuring that the tag is present and has numeric type (all but TIFF\_UNDEFINED and TIFF\_ASCII).

---

## getFieldAsDouble

```
public double getFieldAsDouble(int tag)
```

Returns the value of index 0 of a given tag as a double. The caller is responsible for ensuring that the tag is present and has numeric type (all but TIFF\_UNDEFINED and TIFF\_ASCII).

---

## **readShort**

```
private short readShort(SeekableStream stream)
    throws java.io.IOException
```

---

## **readUnsignedShort**

```
private int readUnsignedShort(SeekableStream stream)
    throws java.io.IOException
```

---

## **readInt**

```
private int readInt(SeekableStream stream)
    throws java.io.IOException
```

---

## **readUnsignedInt**

```
private long readUnsignedInt(SeekableStream stream)
    throws java.io.IOException
```

---

## **readLong**

```
private long readLong(SeekableStream stream)
    throws java.io.IOException
```

---

## **readFloat**

```
private float readFloat(SeekableStream stream)
    throws java.io.IOException
```

---

## **readDouble**

```
private double readDouble(SeekableStream stream)
    throws java.io.IOException
```

---

## **readUnsignedShort**

```
private static int readUnsignedShort(SeekableStream stream,
    boolean isBigEndian)
    throws java.io.IOException
```

---

## **readUnsignedInt**

```
private static long readUnsignedInt(SeekableStream stream,
    boolean isBigEndian)
    throws java.io.IOException
```

---

## **getNumDirectories**

```
public static int getNumDirectories(SeekableStream stream)
    throws java.io.IOException
```

Returns the number of image directories (subimages) stored in a given TIFF file, represented by a `SeekableStream`.

---

## **isBigEndian**

```
public boolean isBigEndian()
```

Returns a boolean indicating whether the byte order used in the the TIFF file is big-endian (i.e. whether the byte order is from the most significant to the least significant)

---

**com.sun.media.jai.codec**  
**Class TIFFEncodeParam**

```
java.lang.Object
|
+--com.sun.media.jai.codec.TIFFEncodeParam
```

---

```
public class TIFFEncodeParam
    extends java.lang.Object
    implements ImageEncodeParam
```

An instance of ImageEncodeParam for encoding images in the TIFF format.

This class allows for the specification of encoding parameters. By default, the image is encoded without any compression, and is written out consisting of strips, not tiles. The particular compression scheme to be used can be specified by using the setCompression method. The compression scheme specified will be honored only if it is compatible with the type of image being written out. For example, Group3 and Group4 compressions can only be used with Bilevel images. Writing of tiled TIFF images can be enabled by calling the setWriteTiled method.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

---

<b>Field Detail</b>
---------------------

**COMPRESSION\_NONE**

```
public static final int COMPRESSION_NONE
```

---

**COMPRESSION\_PACKBITS**

```
public static final int COMPRESSION_PACKBITS
```

---

**COMPRESSION\_GROUP3\_1D**

```
public static final int COMPRESSION_GROUP3_1D
```

---

**COMPRESSION\_GROUP3\_2D**

```
public static final int COMPRESSION_GROUP3_2D
```

---

**COMPRESSION\_GROUP4**

```
public static final int COMPRESSION_GROUP4
```

---

**COMPRESSION\_LZW**

```
public static final int COMPRESSION_LZW
```

---

**compression**

```
private int compression
```

---

**writeTiled**

```
private boolean writeTiled
```

---

<b>Constructor Detail</b>
---------------------------

## TIFFEncodeParam

public **TIFFEncodeParam**()

Constructs an TIFFEncodeParam object with default values for parameters.

### Method Detail

#### getCompression

public int **getCompression**()

Returns the value of the compression parameter.

---

#### setCompression

public void **setCompression**(int compression)

Specifies the type of compression to be used. The compression type specified will be honored only if it is compatible with the image being written out.

**Parameters:**

compression - The compression type.

---

#### getWriteTiled

public boolean **getWriteTiled**()

Returns the value of the writeTiled parameter.

---

#### setWriteTiled

public void **setWriteTiled**(boolean writeTiled)

If set, the data will be written out in tiled format, instead of in strips.

**Parameters:**

writeTiled - Specifies whether the image data should be written out in tiled format.

---

**com.sun.media.jai.codec**

## **Class TIFFField**

java.lang.Object

|--com.sun.media.jai.codec.TIFFField

---

public class **TIFFField**  
extends java.lang.Object

A class representing a field in a TIFF 6.0 Image File Directory.

The TIFF file format is described in more detail in the comments for the TIFFDescriptor class.

A field in a TIFF Image File Directory (IFD). A field is defined as a sequence of values of identical data type. TIFF 6.0 defines 12 data types, which are mapped internally onto the Java datatypes byte, int, long, float, and double.

**This class is not a committed part of the JAI API. It may be removed or changed in future releases of JAI.**

**See Also:**

TIFFDescriptor, TIFFDirectory

---

### **Field Detail**

#### **TIFF\_BYTE**

public static final int **TIFF\_BYTE**

Flag for 8 bit unsigned integers.

---

#### **TIFF\_ASCII**

public static final int **TIFF\_ASCII**

Flag for null-terminated ASCII strings.

---

#### **TIFF\_SHORT**

public static final int **TIFF\_SHORT**

Flag for 16 bit unsigned integers.

---

#### **TIFF\_LONG**

public static final int **TIFF\_LONG**

Flag for 32 bit unsigned integers.

---

#### **TIFF\_RATIONAL**

public static final int **TIFF\_RATIONAL**

Flag for pairs of 32 bit unsigned integers.

---

#### **TIFF\_SBYTE**

public static final int **TIFF\_SBYTE**

Flag for 8 bit signed integers.

---

#### **TIFF\_UNDEFINED**

public static final int **TIFF\_UNDEFINED**

Flag for 8 bit uninterpreted bytes.

---

**TIFF\_SSHORT**

public static final int **TIFF\_SSHORT**  
Flag for 16 bit signed integers.

---

**TIFF\_SLONG**

public static final int **TIFF\_SLONG**  
Flag for 32 bit signed integers.

---

**TIFF\_SRATIONAL**

public static final int **TIFF\_SRATIONAL**  
Flag for pairs of 32 bit signed integers.

---

**TIFF\_FLOAT**

public static final int **TIFF\_FLOAT**  
Flag for 32 bit IEEE floats.

---

**TIFF\_DOUBLE**

public static final int **TIFF\_DOUBLE**  
Flag for 64 bit IEEE doubles.

---

**tag**

int **tag**  
The tag number.

---

**type**

int **type**  
The tag type.

---

**count**

int **count**  
The number of data items present in the field.

---

**data**

java.lang.Object **data**  
The field data.

Constructor Detail

**TIFFField**

**TIFFField()**  
The default constructor.

---

**TIFFField**

```
public TIFFField(int tag,
                 int type,
                 int count,
                 java.lang.Object data)
```

Constructs a TIFFField with arbitrary data. The data parameter must be an array of a Java type appropriate for the type of the TIFF field. Since there is no available 32-bit unsigned datatype, long is used. The mapping between types is as follows:

TIFF type	Java type
TIFF_BYTE	byte
TIFF_ASCII	String
TIFF_SHORT	char
TIFF_LONG	long
TIFF_RATIONAL	long[ 2 ]
TIFF_SBYTE	byte
TIFF_UNDEFINED	byte
TIFF_SSHORT	short
TIFF_SLONG	int
TIFF_SRATIONAL	int[ 2 ]
TIFF_FLOAT	float
TIFF_DOUBLE	double

## Method Detail

### getTag

```
public int getTag()
```

Returns the tag number, between 0 and 65535.

### getType

```
public int getType()
```

Returns the type of the data stored in the IFD. For a TIFF6.0 file, the value will equal one of the TIFF\_ constants defined in this class. For future revisions of TIFF, higher values are possible.

### getCount

```
public int getCount()
```

Returns the number of elements in the IFD.

### getAsBytes

```
public byte[] getAsBytes()
```

Returns the data as an uninterpreted array of bytes. The type of the field must be one of TIFF\_BYTE, TIFF\_SBYTE, or TIFF\_UNDEFINED;

For data in TIFF\_BYTE format, the application must take care when promoting the data to longer integral types to avoid sign extension.

A ClassCastException will be thrown if the field is not of type TIFF\_BYTE, TIFF\_SBYTE, or TIFF\_UNDEFINED.

## getAsChars

```
public char[] getAsChars()
```

Returns TIFF\_SHORT data as an array of chars (unsigned 16-bit integers).

A ClassCastException will be thrown if the field is not of type TIFF\_SHORT.

---

## getAsShorts

```
public short[] getAsShorts()
```

Returns TIFF\_SSHORT data as an array of shorts (signed 16-bit integers).

A ClassCastException will be thrown if the field is not of type TIFF\_SSHORT.

---

## getAsInts

```
public int[] getAsInts()
```

Returns TIFF\_SLONG data as an array of ints (signed 32-bit integers).

A ClassCastException will be thrown if the field is not of type TIFF\_SLONG.

---

## getAsLongs

```
public long[] getAsLongs()
```

Returns TIFF\_LONG data as an array of longs (signed 64-bit integers).

A ClassCastException will be thrown if the field is not of type TIFF\_LONG.

---

## getAsFloats

```
public float[] getAsFloats()
```

Returns TIFF\_FLOAT data as an array of floats.

A ClassCastException will be thrown if the field is not of type TIFF\_FLOAT.

---

## getAsDoubles

```
public double[] getAsDoubles()
```

Returns TIFF\_DOUBLE data as an array of doubles.

A ClassCastException will be thrown if the field is not of type TIFF\_DOUBLE.

---

## getAsSRationals

```
public int[][] getAsSRationals()
```

Returns TIFF\_SRATIONAL data as an array of 2-element arrays of ints.

A ClassCastException will be thrown if the field is not of type TIFF\_SRATIONAL.

---

## getAsRationals

```
public long[][] getAsRationals()
```

Returns TIFF\_RATIONAL data as an array of 2-element arrays of longs.

A ClassCastException will be thrown if the field is not of type TIFF\_RATTIONAL.

---

## getAsInt

```
public int getAsInt(int index)
```

Returns data in TIFF\_BYTE, TIFF\_SBYTE, TIFF\_UNDEFINED, TIFF\_SHORT, TIFF\_SSHORT, or TIFF\_SLONG format as an int.

TIFF\_BYTE and TIFF\_UNDEFINED data are treated as unsigned; that is, no sign extension will take place and the returned value will be in the range [0, 255]. TIFF\_SBYTE data will be returned in the range [-128, 127].

A ClassCastException will be thrown if the field is not of type TIFF\_BYTE, TIFF\_SBYTE, TIFF\_UNDEFINED, TIFF\_SHORT, TIFF\_SSHORT, or TIFF\_SLONG.

---

## getAsLong

```
public long getAsLong(int index)
```

Returns data in TIFF\_BYTE, TIFF\_SBYTE, TIFF\_UNDEFINED, TIFF\_SHORT, TIFF\_SSHORT, TIFF\_SLONG, or TIFF\_LONG format as a long.

TIFF\_BYTE and TIFF\_UNDEFINED data are treated as unsigned; that is, no sign extension will take place and the returned value will be in the range [0, 255]. TIFF\_SBYTE data will be returned in the range [-128, 127].

A ClassCastException will be thrown if the field is not of type TIFF\_BYTE, TIFF\_SBYTE, TIFF\_UNDEFINED, TIFF\_SHORT, TIFF\_SSHORT, TIFF\_SLONG, or TIFF\_LONG.

---

## getAsFloat

```
public float getAsFloat(int index)
```

Returns data in any numerical format as a float. Data in TIFF\_SRATIONAL or TIFF\_RATIONAL format are evaluated by dividing the numerator into the denominator using double-precision arithmetic and then truncating to single precision. Data in TIFF\_SLONG, TIFF\_LONG, or TIFF\_DOUBLE format may suffer from truncation.

A ClassCastException will be thrown if the field is of type TIFF\_UNDEFINED or TIFF\_ASCII.

---

## getAsDouble

```
public double getAsDouble(int index)
```

Returns data in any numerical format as a float. Data in TIFF\_SRATIONAL or TIFF\_RATIONAL format are evaluated by dividing the numerator into the denominator using double-precision arithmetic.

A ClassCastException will be thrown if the field is of type TIFF\_UNDEFINED or TIFF\_ASCII.

---

## getAsString

```
public java.lang.String getAsString(int index)
```

Returns a TIFF\_ASCII data item as a String.

A ClassCastException will be thrown if the field is not of type TIFF\_ASCII.

---

## getAsSRational

```
public int[] getAsSRational(int index)
```

Returns a TIFF\_SRATIONAL data item as a two-element array of ints.

A ClassCastException will be thrown if the field is not of type TIFF\_SRATIONAL.

---

## getAsRational

```
public long[] getAsRational(int index)
```

Returns a TIFF\_RATIONAL data item as a two-element array of ints.

A ClassCastException will be thrown if the field is not of type TIFF\_RATIONAL.

<

() - Static method in class javax.media.jai.PlanarImage

() - Static method in class javax.media.jai.RenderedOp

() - Static method in class com.sun.media.jai.codec.ImageCodec  
Load the JPEG and PNM codecs.

---

## A

**A** - Static variable in class javax.media.jai.InterpolationBicubic2

**A** - Static variable in class javax.media.jai.InterpolationBicubic

**A0** - Static variable in class javax.media.jai.InterpolationBicubic2

**A0** - Static variable in class javax.media.jai.InterpolationBicubic

**A2** - Static variable in class javax.media.jai.InterpolationBicubic2

**A2** - Static variable in class javax.media.jai.InterpolationBicubic

**A3** - Static variable in class javax.media.jai.InterpolationBicubic2

**A3** - Static variable in class javax.media.jai.InterpolationBicubic

**abs(int)** - Static method in class com.sun.media.jai.codec.PNGEncodeParam  
An abs() function for use by the Paeth predictor.

**AbsoluteDescriptor** - class javax.media.jai.operator.AbsoluteDescriptor.  
An OperationDescriptor describing the "Absolute" operation.

**AbsoluteDescriptor()** - Constructor for class javax.media.jai.operator.AbsoluteDescriptor  
Constructor.

**accumulateStatistics(String, Raster, Object)** - Method in class javax.media.jai.StatisticsOpImage  
Accumulates statistics on the specified region into the previously created statistics object.

**activeTiles** - Variable in class javax.media.jai.SnapshotImage  
The set of active tiles, represented as a HashSet of Points.

**add(Object)** - Method in class javax.media.jai.CollectionImage  
Adds the specified object to this collection.

**add(Object)** - Method in class javax.media.jai.ImageSequence  
Adds a SequentialImage to this collection.

**add(Object)** - Method in class javax.media.jai.ImageStack  
Adds a CoordinateImage to this collection.

**add(Object)** - Method in class javax.media.jai.CollectionOp  
Adds the specified object to this collection.

**add(RenderedImage, int, int, Raster)** - Method in interface javax.media.jai.TileCache  
Adds a tile to the cache.

**add(ROI)** - Method in class javax.media.jai.ROI  
Adds another ROI to this one and returns the result as a new ROI.

**add(ROI)** - Method in class javax.media.jai.ROIShape  
Adds another mask to this one.

**addAll(Collection)** - Method in class javax.media.jai.CollectionImage  
Adds all of the elements in the specified collection to this collection.

**addAll(Collection)** - Method in class javax.media.jai.CollectionOp  
Adds all of the elements in the specified collection to this collection.

**addCIF(CollectionImageFactory)** - Method in class javax.media.jai.OperationGraph  
Adds a CIF to an OperationGraph.

**AddCollectionDescriptor** - class javax.media.jai.operator.AddCollectionDescriptor.  
An OperationDescriptor describing the "AddCollection" operation.

**AddCollectionDescriptor()** - Constructor for class javax.media.jai.operator.AddCollectionDescriptor  
Constructor.

**AddConstDescriptor** - class javax.media.jai.operator.AddConstDescriptor.  
An OperationDescriptor describing the "AddConst" operation.

**AddConstDescriptor()** - Constructor for class javax.media.jai.operator.AddConstDescriptor  
Constructor.

**AddConstToCollectionDescriptor** - class javax.media.jai.operator.AddConstToCollectionDescriptor.  
An `OperationDescriptor` describing the "AddConstToCollection" operation.

**AddConstToCollectionDescriptor()** - Constructor for class javax.media.jai.operator.AddConstToCollectionDescriptor  
Constructor.

**AddDescriptor** - class javax.media.jai.operator.AddDescriptor.  
An `OperationDescriptor` describing the "Add" operation.

**AddDescriptor()** - Constructor for class javax.media.jai.operator.AddDescriptor  
Constructor.

**addEdge(PartialOrderNode)** - Method in class javax.media.jai.PartialOrderNode  
Adds a directed edge to the graph.

**addNodeSource(Object)** - Method in class javax.media.jai.RenderedOp  
Adds a source to the `ParameterBlock` of this node.

**addNotify()** - Method in class javax.media.jai.widget.ImageCanvas

**addPrivateChunk(String, byte[])** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Adds a private chunk, in binary form, to the list of chunks to be stored with this image.

**addProduct(String)** - Method in class javax.media.jai.ProductOperationGraph  
Adds a product to an `ProductOperationGraph`.

**addPropertyGenerator(PropertyGenerator)** - Method in class javax.media.jai.RenderedOp  
Adds a `PropertyGenerator` to the node.

**addPropertyGenerator(PropertyGenerator)** - Method in class javax.media.jai.RenderableOp  
Adds a `PropertyGenerator` to the node.

**addPropertyGenerator(PropertyGenerator)** - Method in class javax.media.jai.PropertySourceImpl

**addPropertyGenerator(String, PropertyGenerator)** - Method in class javax.media.jai.OperationRegistry  
Adds a `PropertyGenerator` to the registry, associating it with a particular `OperationDescriptor`.

**addRenderingHints(Map)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**addRenderingHints(Map)** - Method in class javax.media.jai.TiledImageGraphics

**addRenderingHints(Map)** - Method in class javax.media.jai.RenderableGraphics

**addRIF(RenderedImageFactory)** - Method in class javax.media.jai.OperationGraph  
Adds a RIF to an `OperationGraph`.

**addSink(PlanarImage)** - Method in class javax.media.jai.PlanarImage  
Adds a `PlanarImage` sink to the list of sinks.

**addSink(PlanarImage)** - Method in class javax.media.jai.RenderedOp  
Renders the node if it has not already been rendered, and adds a `PlanarImage` sink to the list of sinks of the rendered image.

**addSource(PlanarImage)** - Method in class javax.media.jai.PlanarImage  
Adds a `PlanarImage` source to the list of sources.

**addSource(PlanarImage)** - Method in class javax.media.jai.RenderedOp  
Renders the node if it has not already been rendered, and adds a `PlanarImage` source to the list of sources of the rendered image.

**addTile(Raster, int, int)** - Method in class javax.media.jai.Snapshot  
Stores a given tile in this `Snapshot`.

**addTileObserver(TileObserver)** - Method in class javax.media.jai.WritableRenderedImageAdapter  
Add an observer.

**addTileObserver(TileObserver)** - Method in class javax.media.jai.TiledImage  
Informs this `TiledImage` that another object is interested in being notified whenever any tile becomes writable or ceases to be writable.

**addTileToCache(int, int, Raster)** - Method in class javax.media.jai.OpImage  
Adds a tile at a given location to the cache.

**addViewportListener(ViewportListener)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Adds the specified `ViewportListener` to the panel

**adjustedOffset** - Variable in class javax.media.jai.ColorCube  
An offset into the lookup table, accounting for negative dimensions.

**adjustmentValueChanged(AdjustmentEvent)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Called by the AWT when either scrollbar changes.

**AffineDescriptor** - class javax.media.jai.operator.AffineDescriptor.  
An `OperationDescriptor` describing the "Affine" operation.

**AffineDescriptor()** - Constructor for class javax.media.jai.operator.AffineDescriptor  
Constructor.

**AffinePropertyGenerator** - class javax.media.jai.operator.AffinePropertyGenerator.  
This property generator computes the properties for the operation "Affine" dynamically.

**AffinePropertyGenerator()** - Constructor for class javax.media.jai.operator.AffinePropertyGenerator  
 Constructor.

**alpha** - Variable in class com.sun.media.jai.codec.PNGSuggestedPaletteEntry  
 The alpha opacity value of the entry.

**ancestorSampleModel** - Variable in class javax.media.jai.TiledImage

**AndConstDescriptor** - class javax.media.jai.operator.AndConstDescriptor.  
 An OperationDescriptor describing the "AndConst" operation.

**AndConstDescriptor()** - Constructor for class javax.media.jai.operator.AndConstDescriptor  
 Constructor.

**AndDescriptor** - class javax.media.jai.operator.AndDescriptor.  
 An OperationDescriptor describing the "And" operation.

**AndDescriptor()** - Constructor for class javax.media.jai.operator.AndDescriptor  
 Constructor.

**appendEdge(Vector, int, int)** - Method in class javax.media.jai.ROIShape.PolyShape  
 Append a PolyEdge to the Vector of active edges.

**AreaOpImage** - class javax.media.jai.AreaOpImage.  
 An abstract base class for image operators that require only a fixed rectangular source region around a source pixel in order to compute each destination pixel.

**AreaOpImage(RenderedImage, BorderExtender, TileCache, ImageLayout, int, int, int, int, boolean)** - Constructor for class javax.media.jai.AreaOpImage  
 Constructs an AreaOpImage.

**areFieldsInitialized** - Variable in class javax.media.jai.PointOpImage

**args** - Variable in class javax.media.jai.CollectionOp  
 The input arguments for this operation, including sources and/or parameters.

**aspect** - Variable in class javax.media.jai.MultiResolutionRenderableImage  
 The aspect ratio, derived from the highest-resolution source.

**available()** - Method in class com.sun.media.jai.codec.ForwardSeekableStream  
 Forwards the request to the real InputStream.

**AWTImageDescriptor** - class javax.media.jai.operator.AWTImageDescriptor.  
 An OperationDescriptor describing the "AWTImage" operation.

**AWTImageDescriptor()** - Constructor for class javax.media.jai.operator.AWTImageDescriptor  
 Constructor.

---

## B

**B0** - Static variable in class javax.media.jai.InterpolationBicubic2

**B0** - Static variable in class javax.media.jai.InterpolationBicubic

**B1** - Static variable in class javax.media.jai.InterpolationBicubic2

**B1** - Static variable in class javax.media.jai.InterpolationBicubic

**B2** - Static variable in class javax.media.jai.InterpolationBicubic2

**B2** - Static variable in class javax.media.jai.InterpolationBicubic

**B3** - Static variable in class javax.media.jai.InterpolationBicubic2

**B3** - Static variable in class javax.media.jai.InterpolationBicubic

**background** - Variable in class javax.media.jai.TiledImageGraphics

**background** - Variable in class javax.media.jai.RenderableGraphics

**backgroundColor** - Variable in class javax.media.jai.widget.ImageCanvas

**backgroundPaletteGray** - Variable in class com.sun.media.jai.codec.PNGEncodeParam.Gray

**backgroundPaletteIndex** - Variable in class com.sun.media.jai.codec.PNGEncodeParam.Palette

**backgroundRGB** - Variable in class com.sun.media.jai.codec.PNGEncodeParam.RGB

**backgroundSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam.Palette

**backgroundSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam.Gray

**backgroundSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam.RGB

**BandCombineDescriptor** - class javax.media.jai.operator.BandCombineDescriptor.  
An `OperationDescriptor` describing the "BandCombine" operation.

**BandCombineDescriptor()** - Constructor for class javax.media.jai.operator.BandCombineDescriptor  
Constructor.

**bandDataOffsets** - Variable in class javax.media.jai.RasterAccessor  
The bandOffset + subRasterOffset + DataBufferOffset into each of the numBand data arrays

**bandList** - Variable in class javax.media.jai.TiledImage

**bandOffsets** - Variable in class javax.media.jai.RasterFormatTag

**bandOffsets** - Variable in class javax.media.jai.RasterAccessor  
Offset from a pixel's offset to a band of that pixel

**BandSelectDescriptor** - class javax.media.jai.operator.BandSelectDescriptor.  
An `OperationDescriptor` describing the "BandSelect" operation.

**BandSelectDescriptor()** - Constructor for class javax.media.jai.operator.BandSelectDescriptor  
Constructor.

**bankdata** - Variable in class javax.media.jai.DataBufferDouble  
The array of data banks.

**bankdata** - Variable in class javax.media.jai.DataBufferFloat  
The array of data banks.

**bankIndices** - Variable in class javax.media.jai.RasterFormatTag

**beingDragged** - Variable in class javax.media.jai.widget.ScrollingImagePanel  
True if we are in the middle of a mouse drag.

**bicubic(float)** - Static method in class javax.media.jai.InterpolationBicubic2  
Returns the bicubic polynomial value at a certain value of x.

**bicubic(float)** - Static method in class javax.media.jai.InterpolationBicubic  
Returns the bicubic polynomial value at a certain value of x.

**bicubic2Instance** - Static variable in class javax.media.jai.Interpolation

**bicubicInstance** - Static variable in class javax.media.jai.Interpolation

**bilinearInstance** - Static variable in class javax.media.jai.Interpolation

**bins** - Variable in class javax.media.jai.Histogram  
The bins for each band, used to hold information about pixel vlaues.

**binWidth** - Variable in class javax.media.jai.Histogram

**bitDepth** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**bitDepthSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**bitsHelper(int, ColorSpace, boolean)** - Static method in class javax.media.jai.FloatDoubleColorModel

**bitShift** - Variable in class com.sun.media.jai.codec.PNGEncodeParam.Gray

**bitShiftSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam.Gray

**blue** - Variable in class com.sun.media.jai.codec.PNGSuggestedPaletteEntry  
The blue color value of the entry.

**BMPDescriptor** - class javax.media.jai.operator.BMPDescriptor.  
An `OperationDescriptor` describing the "BMP" operation.

**BMPDescriptor()** - Constructor for class javax.media.jai.operator.BMPDescriptor  
Constructor.

**BMPEncodeParam** - class com.sun.media.jai.codec.BMPEncodeParam.  
An instance of `ImageEncodeParam` for encoding images in the BMP format.

**BMPEncodeParam()** - Constructor for class com.sun.media.jai.codec.BMPEncodeParam  
Constructs an `BMPEncodeParam` object with default values for parameters.

**BORDER\_CONST\_FILL** - Static variable in class javax.media.jai.operator.BorderDescriptor

**BORDER\_COPY** - Static variable in class javax.media.jai.BorderExtender  
A constant for use in the `createInstance` method.

**BORDER\_EXTEND** - Static variable in class javax.media.jai.operator.BorderDescriptor

**BORDER\_REFLECT** - Static variable in class javax.media.jai.BorderExtender  
A constant for use in the `createInstance` method.

**BORDER\_REFLECT** - Static variable in class javax.media.jai.operator.BorderDescriptor

**BORDER\_WRAP** - Static variable in class javax.media.jai.BorderExtender  
A constant for use in the `createInstance` method.

**BORDER\_WRAP** - Static variable in class javax.media.jai.operator.BorderDescriptor

**BORDER\_ZERO** - Static variable in class javax.media.jai.BorderExtender  
A constant for use in the `createInstance` method.

**BORDER\_ZERO\_FILL** - Static variable in class javax.media.jai.operator.BorderDescriptor

**BorderDescriptor** - class javax.media.jai.operator.BorderDescriptor.  
An `OperationDescriptor` describing the "Border" operation.

**BorderDescriptor()** - Constructor for class javax.media.jai.operator.BorderDescriptor  
Constructor.

**BorderExtender** - class javax.media.jai.BorderExtender.  
An abstract superclass for classes that extend a `WritableRaster` with additional pixel data taken from a `PlanarImage`.

**BorderExtender()** - Constructor for class javax.media.jai.BorderExtender

**BorderExtenderConstant** - class javax.media.jai.BorderExtenderConstant.  
A subclass of `BorderExtender` that implements border extension by filling all pixels outside of the image bounds with constant values.

**BorderExtenderConstant(double[])** - Constructor for class javax.media.jai.BorderExtenderConstant  
Constructs an instance of `BorderExtenderConstant` with a given set of constants.

**borderExtenderCopy** - Static variable in class javax.media.jai.BorderExtender

**BorderExtenderCopy** - class javax.media.jai.BorderExtenderCopy.  
A subclass of `BorderExtender` that implements border extension by filling all pixels outside of the image bounds with copies of the edge pixels.

**BorderExtenderCopy()** - Constructor for class javax.media.jai.BorderExtenderCopy

**borderExtenderReflect** - Static variable in class javax.media.jai.BorderExtender

**BorderExtenderReflect** - class javax.media.jai.BorderExtenderReflect.  
A subclass of `BorderExtender` that implements border extension by filling all pixels outside of the image bounds with copies of the whole image.

**BorderExtenderReflect()** - Constructor for class javax.media.jai.BorderExtenderReflect

**borderExtenderWrap** - Static variable in class javax.media.jai.BorderExtender

**BorderExtenderWrap** - class javax.media.jai.BorderExtenderWrap.  
A subclass of `BorderExtender` that implements border extension by filling all pixels outside of the image bounds with copies of the whole image.

**BorderExtenderWrap()** - Constructor for class javax.media.jai.BorderExtenderWrap

**borderExtenderZero** - Static variable in class javax.media.jai.BorderExtender

**BorderExtenderZero** - class javax.media.jai.BorderExtenderZero.  
A subclass of `BorderExtender` that implements border extension by filling all pixels outside of the image bounds with zeros.

**BorderExtenderZero()** - Constructor for class javax.media.jai.BorderExtenderZero

**bottomPadding** - Variable in class javax.media.jai.Interpolation  
The number of pixels lying below the interpolation kernel key position.

**bottomPadding** - Variable in class javax.media.jai.AreaOpImage  
The number of source pixels needed below the central pixel.

**boundingBox** - Variable in class javax.media.jai.RenderableOp

**BoxFilterDescriptor** - class javax.media.jai.operator.BoxFilterDescriptor.  
An `OperationDescriptor` describing the "BoxFilter" operation.

**BoxFilterDescriptor()** - Constructor for class javax.media.jai.operator.BoxFilterDescriptor  
 Constructor.

**bpad** - Variable in class javax.media.jai.ScaleOpImage

**buf** - Variable in class com.sun.media.jai.codec.FileCacheSeekableStream  
 The read buffer.

**bufLen** - Variable in class com.sun.media.jai.codec.FileCacheSeekableStream  
 The length of the read buffer.

**BYTE\_496** - Static variable in class javax.media.jai.ColorCube  
 A ColorCube for dithering RGB byte data into 216 colors.

**BYTE\_855** - Static variable in class javax.media.jai.ColorCube  
 A ColorCube for dithering YCC byte data into 200 colors.

**ByteArraySeekableStream** - class com.sun.media.jai.codec.ByteArraySeekableStream.  
 A subclass of SeekableStream that takes input from an array of bytes.

**ByteArraySeekableStream(byte[])** - Constructor for class com.sun.media.jai.codec.ByteArraySeekableStream  
 Constructs a ByteArraySeekableStream taking input from an entire input byte array.

**ByteArraySeekableStream(byte[], int, int)** - Constructor for class com.sun.media.jai.codec.ByteArraySeekableStream  
 Constructs a ByteArraySeekableStream taking input from a given segment of an input byte array.

**byteDataArrays** - Variable in class javax.media.jai.RasterAccessor  
 The image data in a two-dimensional byte array.

---

## C

**c1** - Variable in class javax.media.jai.WarpQuadratic

**c1** - Variable in class javax.media.jai.WarpAffine

**c1** - Variable in class javax.media.jai.WarpCubic

**c10** - Variable in class javax.media.jai.WarpQuadratic

**c10** - Variable in class javax.media.jai.WarpCubic

**c11** - Variable in class javax.media.jai.WarpQuadratic

**c11** - Variable in class javax.media.jai.WarpCubic

**c12** - Variable in class javax.media.jai.WarpQuadratic

**c12** - Variable in class javax.media.jai.WarpCubic

**c13** - Variable in class javax.media.jai.WarpCubic

**c14** - Variable in class javax.media.jai.WarpCubic

**c15** - Variable in class javax.media.jai.WarpCubic

**c16** - Variable in class javax.media.jai.WarpCubic

**c17** - Variable in class javax.media.jai.WarpCubic

**c18** - Variable in class javax.media.jai.WarpCubic

**c19** - Variable in class javax.media.jai.WarpCubic

**c2** - Variable in class javax.media.jai.WarpQuadratic

**c2** - Variable in class javax.media.jai.WarpAffine

**c2** - Variable in class javax.media.jai.WarpCubic

**c20** - Variable in class javax.media.jai.WarpCubic

**c3** - Variable in class javax.media.jai.WarpQuadratic

**c3** - Variable in class javax.media.jai.WarpAffine

**c3** - Variable in class javax.media.jai.WarpCubic

**c4** - Variable in class javax.media.jai.WarpQuadratic

**c4** - Variable in class javax.media.jai.WarpAffine

**c4** - Variable in class javax.media.jai.WarpCubic

**c5** - Variable in class javax.media.jai.WarpQuadratic

**c5** - Variable in class javax.media.jai.WarpAffine

**c5** - Variable in class javax.media.jai.WarpCubic

**c6** - Variable in class javax.media.jai.WarpQuadratic

**c6** - Variable in class javax.media.jai.WarpAffine

**c6** - Variable in class javax.media.jai.WarpCubic

**c7** - Variable in class javax.media.jai.WarpQuadratic

**c7** - Variable in class javax.media.jai.WarpCubic

**c8** - Variable in class javax.media.jai.WarpQuadratic

**c8** - Variable in class javax.media.jai.WarpCubic

**c9** - Variable in class javax.media.jai.WarpQuadratic

**c9** - Variable in class javax.media.jai.WarpCubic

**cache** - Variable in class javax.media.jai.OpImage  
A reference to a centralized TileCache object.

**cache** - Variable in class com.sun.media.jai.codec.FileCacheSeekableStream  
The cache as a RandomAccessFile.

**cacheFile** - Variable in class com.sun.media.jai.codec.FileCacheSeekableStream  
The cache File.

**cameraPosition** - Variable in class javax.media.jai.SequentialImage  
The camera position associated with the image.

**canEncodeImage(RenderedImage, ImageEncodeParam)** - Method in class com.sun.media.jai.codec.ImageCodec  
Returns true if the given image and encoder param object are suitable for encoding by this ImageCodec.

**canSeekBackwards** - Variable in class com.sun.media.jai.codec.SegmentedSeekableStream

**canSeekBackwards()** - Method in class com.sun.media.jai.codec.SeekableStream  
Returns true if this object supports calls to seek(pos) with an offset pos smaller than the current offset, as returned by getFilePointer.

**canSeekBackwards()** - Method in class com.sun.media.jai.codec.ForwardSeekableStream  
Returns false since seeking backwards is not supported.

**canSeekBackwards()** - Method in class com.sun.media.jai.codec.SegmentedSeekableStream  
Returns true if seeking backwards is supported.

**canSeekBackwards()** - Method in class com.sun.media.jai.codec.ByteArraySeekableStream  
Returns true since this object supports seeking backwards.

**canSeekBackwards()** - Method in class com.sun.media.jai.codec.MemoryCacheSeekableStream  
Returns true since all MemoryCacheSeekableStream instances support seeking backwards.

**canSeekBackwards()** - Method in class com.sun.media.jai.codec.FileCacheSeekableStream  
Returns true since all FileCacheSeekableStream instances support seeking backwards.

**canSeekBackwards()** - Method in class com.sun.media.jai.codec.FileSeekableStream  
Returns true since seeking backwards is supported.

**canvasHeight** - Variable in class javax.media.jai.widget.ImageCanvas  
The height of the canvas.

**CanvasJAI** - class javax.media.jai.CanvasJAI.  
An extension of java.awt.Canvas for use with JAI.

**CanvasJAI(GraphicsConfiguration)** - Constructor for class javax.media.jai.CanvasJAI  
Constructs an instance of CanvasJAI using the given GraphicsConfiguration.

**canvasWidth** - Variable in class javax.media.jai.widget.ImageCanvas  
The width of the canvas.

**capacity** - Variable in class javax.media.jai.IntegerSequence  
The capacity of iArray.

**checkInPlaceOperation** - Variable in class javax.media.jai.PointOpImage

**checkSeparable()** - Method in class javax.media.jai.KernelJAI

**checkVersion(int)** - Method in class com.sun.media.jai.codec.BMPEncodeParam

**chromaticity** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**chromaticitySet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**chunkData** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**chunkType** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**cifcount** - Variable in class javax.media.jai.OperationRegistry

**CIFoperations** - Variable in class javax.media.jai.OperationGraph  
A Vector of CIF implementations.

**cifPref** - Variable in class javax.media.jai.RegistryInitData

**cifPrefs** - Variable in class javax.media.jai.OperationRegistry  
A Hashtable of all the CIF preferences, hashed by the operation name that the CIF belongs to.

**cifs** - Variable in class javax.media.jai.OperationRegistry  
Same as above three structures, but for CIFs.

**cifsByName** - Variable in class javax.media.jai.OperationRegistry

**cifTable** - Variable in class javax.media.jai.RegistryInitData

**clamp(double)** - Method in class javax.media.jai.FloatDoubleColorModel

**clamp(float)** - Method in class javax.media.jai.FloatDoubleColorModel

**clamp(int, int, int)** - Method in class javax.media.jai.BorderExtenderConstant

**clampDataArray(double[], double[])** - Method in class javax.media.jai.RasterAccessor

**clampDataArrays()** - Method in class javax.media.jai.RasterAccessor  
Clamps data array values to a range that the underlying raster can deal with.

**ClampDescriptor** - class javax.media.jai.operator.ClampDescriptor.  
An OperationDescriptor describing the "Clamp" operation.

**ClampDescriptor()** - Constructor for class javax.media.jai.operator.ClampDescriptor  
Constructor.

**clampDoubleArrays(double[], double[])** - Method in class javax.media.jai.RasterAccessor

**clampFloatArrays(float[], float[])** - Method in class javax.media.jai.RasterAccessor

**clampIntArray(int[], int[])** - Method in class javax.media.jai.RasterAccessor

**classifyKernel()** - Method in class javax.media.jai.KernelJAI

**classifyPolygon()** - Method in class javax.media.jai.ROIShape.PolyShape  
Classify a Polygon as one of the pre-defined types for this class.

**clear()** - Method in class javax.media.jai.CollectionImage  
Removes all of the elements from this collection.

**clear()** - Method in class javax.media.jai.CollectionOp  
Removes all of the elements from this collection.

**clearCIFPreferences(String, String)** - Method in class javax.media.jai.OperationRegistry  
Removes all preferences between CIFs within a product registered under a particular OperationDescriptor.

**clearHistogram()** - Method in class javax.media.jai.Histogram  
Resets the counts of all bins to zero.

**clearOperationPreferences(String, String)** - Method in class javax.media.jai.OperationRegistry  
Removes all RIF and CIF preferences within a product registered under a particular OperationDescriptor.

**clearProductPreferences(String)** - Method in class javax.media.jai.OperationRegistry  
Removes all preferences between products registered under a common OperationDescriptor.

**clearPropertyState()** - Method in class javax.media.jai.OperationRegistry  
Removes all property associated information from this OperationRegistry.

**clearRect(int, int, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**clearRect(int, int, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**clearRect(int, int, int, int)** - Method in class javax.media.jai.RenderableGraphics

**clearRenderingHints()** - Method in class javax.media.jai.JAI  
Clears the RenderingHints associated with this JAI instance.

**clearRIFPreferences(String, String)** - Method in class javax.media.jai.OperationRegistry  
Removes all preferences between RIFs within a product registered under a particular OperationDescriptor.

**clip** - Variable in class javax.media.jai.TiledImageGraphics

**clip** - Variable in class javax.media.jai.RenderableGraphics

**clip** - Variable in class javax.media.jai.ROIShape.PolyShape  
The clipping Rectangle.

**clip(Shape)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**clip(Shape)** - Method in class javax.media.jai.TiledImageGraphics

**clip(Shape)** - Method in class javax.media.jai.RenderableGraphics

**clipRect(int, int, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**clipRect(int, int, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**clipRect(int, int, int, int)** - Method in class javax.media.jai.RenderableGraphics

**clone()** - Method in class javax.media.jai.ImageLayout  
Returns a clone of the ImageLayout as an Object.

**clone()** - Method in class javax.media.jai.PerspectiveTransform  
Returns a copy of this PerspectiveTransform object.

**close()** - Method in class com.sun.media.jai.codec.ForwardSeekableStream  
Forwards the request to the real InputStream.

**close()** - Method in class com.sun.media.jai.codec.ByteArraySeekableStream  
Does nothing.

**close()** - Method in class com.sun.media.jai.codec.FileCacheSeekableStream  
Closes this stream and releases any system resources associated with the stream.

**close()** - Method in class com.sun.media.jai.codec.FileSeekableStream  
Forwards the request to the real File.

**cobbleByte(Rectangle, Raster)** - Method in class javax.media.jai.PlanarImage

**cobbleDouble(Rectangle, Raster)** - Method in class javax.media.jai.PlanarImage

**cobbleFloat(Rectangle, Raster)** - Method in class javax.media.jai.PlanarImage

**cobbleInt(Rectangle, Raster)** - Method in class javax.media.jai.PlanarImage

**cobbleShort(Rectangle, Raster)** - Method in class javax.media.jai.PlanarImage

**cobbleSources** - Variable in class javax.media.jai.OpImage  
Set to true if computeRect needs contiguous sources.

**cobbleUShort(Rectangle, Raster)** - Method in class javax.media.jai.PlanarImage

**codecs** - Static variable in class com.sun.media.jai.codec.ImageCodec

**coerceData(WritableRaster, boolean)** - Method in class javax.media.jai.FloatDoubleColorModel  
Forces the raster data to match the state specified in the isAlphaPremultiplied variable, assuming the data is currently correctly described by this ColorModel.

**CollectionImage** - class javax.media.jai.CollectionImage.  
An abstract superclass for classes representing a collection of images.

**CollectionImage()** - Constructor for class javax.media.jai.CollectionImage  
Default constructor.

**CollectionImage(Collection)** - Constructor for class javax.media.jai.CollectionImage  
Constructs a class that contains an image collection.

**CollectionImageFactory** - interface javax.media.jai.CollectionImageFactory.  
The CollectionImageFactory interface (often abbreviated CIF) is intended to be implemented by classes that wish to act as factories to produce different collection image operators.

**CollectionOp** - class javax.media.jai.CollectionOp.  
A node in either a rendered or a renderable image chain representing a CollectionImage.

**CollectionOp(OperationRegistry, String, ParameterBlock)** - Constructor for class javax.media.jai.CollectionOp  
Constructs a CollectionOp that will be used to instantiate a particular collection operation from a given operation registry, an operation name, and a ParameterBlock There is no rendering hints associated with this operation.

**CollectionOp(OperationRegistry, String, ParameterBlock, RenderingHints)** - Constructor for class javax.media.jai.CollectionOp  
Constructs a CollectionOp that will be used to instantiate a particular collection operation from a given operation registry, an operation name, a ParameterBlock, and a set of rendering hints.

**CollectionOp(String, ParameterBlock, RenderingHints)** - Constructor for class javax.media.jai.CollectionOp  
Constructs a CollectionOp that will be used to instantiate a particular collection operation from a given operation name, a ParameterBlock, and a set of rendering hints.

**color** - Variable in class javax.media.jai.TiledImageGraphics

**color** - Variable in class javax.media.jai.RenderableGraphics

**COLOR\_MODEL\_MASK** - Static variable in class javax.media.jai.ImageLayout  
A bitmask to specify the validity of colorModel.

**ColorConvertDescriptor** - class javax.media.jai.operator.ColorConvertDescriptor.  
An OperationDescriptor describing the "ColorConvert" operation.

**ColorConvertDescriptor()** - Constructor for class javax.media.jai.operator.ColorConvertDescriptor  
Constructor.

**ColorCube** - class javax.media.jai.ColorCube.  
A subclass of LookupTableJAI which represents a lookup table which is a color cube.

**ColorCube(byte[][], int)** - Constructor for class javax.media.jai.ColorCube  
Returns a multi-banded byte ColorCube with an index offset common to all bands.

**ColorCube(double[][], int)** - Constructor for class javax.media.jai.ColorCube  
Returns a multi-banded double ColorCube with an index offset common to all bands.

**ColorCube(float[][], int)** - Constructor for class javax.media.jai.ColorCube  
Returns a multi-banded float ColorCube with an index offset common to all bands.

**ColorCube(int[][], int)** - Constructor for class javax.media.jai.ColorCube  
Returns a multi-banded int ColorCube with an index offset common to all bands.

**ColorCube(short[][], int, boolean)** - Constructor for class javax.media.jai.ColorCube  
Returns a multi-banded short or unsigned short ColorCube with an index offset common to all bands.

**colorModel** - Variable in class javax.media.jai.ImageLayout  
The image's ColorModel.

**colorModel** - Variable in class javax.media.jai.PlanarImage  
The image's ColorModel.

**colorModel** - Variable in class javax.media.jai.TiledImageGraphics

**colorModel** - Variable in class javax.media.jai.widget.ImageCanvas  
The image's ColorModel or one we supply.

**colorModelGray16** - Static variable in class com.sun.media.jai.codec.ImageCodec

**colorModelGray32** - Static variable in class com.sun.media.jai.codec.ImageCodec

**colorModelGray8** - Static variable in class com.sun.media.jai.codec.ImageCodec

**colorModelGrayAlpha16** - Static variable in class com.sun.media.jai.codec.ImageCodec

**colorModelGrayAlpha32** - Static variable in class com.sun.media.jai.codec.ImageCodec

**colorModelGrayAlpha8** - Static variable in class com.sun.media.jai.codec.ImageCodec

**colorModelRGB16** - Static variable in class com.sun.media.jai.codec.ImageCodec

**colorModelRGB32** - Static variable in class com.sun.media.jai.codec.ImageCodec

**colorModelRGB8** - Static variable in class com.sun.media.jai.codec.ImageCodec

**colorModelRGBA16** - Static variable in class com.sun.media.jai.codec.ImageCodec

**colorModelRGBA32** - Static variable in class com.sun.media.jai.codec.ImageCodec

**colorModelRGBA8** - Static variable in class com.sun.media.jai.codec.ImageCodec

**colorSpace** - Variable in class javax.media.jai.FloatDoubleColorModel

**colorSpaceType** - Variable in class javax.media.jai.FloatDoubleColorModel

com.sun.media.jai.codec - package com.sun.media.jai.codec

**combiner** - Variable in class javax.media.jai.ImagePyramid

The operation chain used to combine two images.

**compare(Object, Object)** - Method in class javax.media.jai.ROIShape.PolyShape.PolyEdge  
Implementation of java.util.Comparator.compare.

**COMPLEX\_TO\_COMPLEX** - Static variable in class javax.media.jai.operator.DFTDescriptor  
A flag indicating that the source and destination data are both complex.

**COMPLEX\_TO\_REAL** - Static variable in class javax.media.jai.operator.DFTDescriptor  
A flag indicating that the source data are complex and the destination data real.

**component** - Variable in class javax.media.jai.GraphicsJAI

**componentHidden(ComponentEvent)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Ignored

**componentMoved(ComponentEvent)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Ignored

**componentResized(ComponentEvent)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Called when the ImagePanel is resized

**ComponentSampleModelJAI** - class javax.media.jai.ComponentSampleModelJAI.

This class represents image data which is stored such that each sample of a pixel occupies one data element of the DataBuffer.

**ComponentSampleModelJAI(int, int, int, int, int, int[])** - Constructor for class javax.media.jai.ComponentSampleModelJAI  
Constructs a ComponentSampleModel with the specified parameters.

**ComponentSampleModelJAI(int, int, int, int, int, int[], int[])** - Constructor for class  
javax.media.jai.ComponentSampleModelJAI

Constructs a ComponentSampleModel with the specified parameters.

**componentShown(ComponentEvent)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Ignored

**composite** - Variable in class javax.media.jai.TiledImageGraphics

**composite** - Variable in class javax.media.jai.RenderableGraphics

**CompositeDescriptor** - class javax.media.jai.operator.CompositeDescriptor.

An OperationDescriptor describing the "Composite" operation.

**CompositeDescriptor()** - Constructor for class javax.media.jai.operator.CompositeDescriptor  
Constructor.

**compressed** - Variable in class com.sun.media.jai.codec.BMPEncodeParam

**compression** - Variable in class com.sun.media.jai.codec.TIFFEncodeParam

**COMPRESSION\_GROUP3\_1D** - Static variable in class com.sun.media.jai.codec.TIFFEncodeParam

**COMPRESSION\_GROUP3\_2D** - Static variable in class com.sun.media.jai.codec.TIFFEncodeParam

**COMPRESSION\_GROUP4** - Static variable in class com.sun.media.jai.codec.TIFFEncodeParam

**COMPRESSION\_LZW** - Static variable in class com.sun.media.jai.codec.TIFFEncodeParam

**COMPRESSION\_NONE** - Static variable in class com.sun.media.jai.codec.TIFFEncodeParam

**COMPRESSION\_PACKBITS** - Static variable in class com.sun.media.jai.codec.TIFFEncodeParam

**computeImage(Raster, WritableRaster, Rectangle)** - Method in class javax.media.jai.UntiledOpImage  
Calculate the destination image from the source image.

**computeRect(PlanarImage[], WritableRaster, Rectangle)** - Method in class javax.media.jai.OpImage  
Computes a rectangle of output, given PlanarImage sources.

**computeRect(Raster[], WritableRaster, Rectangle)** - Method in class javax.media.jai.OpImage  
Computes a rectangle of output, given Raster sources.

**computesUniqueTiles()** - Method in class javax.media.jai.OpImage  
Returns true if the OpImage returns a unique Raster object every time computeTile() is called.

**computesUniqueTiles()** - Method in class javax.media.jai.SourcelessOpImage  
Returns false as SourcelessOpImages often return Rasters via computeTile() tile that are internally cached.

**computesUniqueTiles()** - Method in class javax.media.jai.NullOpImage  
Returns false as NullOpImage can return via computeTile() tile that are internally cached.

**computeTile(int, int)** - Method in class javax.media.jai.OpImage  
The internal counterpart of getTile().

**computeTile(int, int)** - Method in class javax.media.jai.SourcelessOpImage  
Computes a tile.

**computeTile(int, int)** - Method in class javax.media.jai.PointOpImage  
Computes a tile.

**computeTile(int, int)** - Method in class javax.media.jai.NullOpImage  
Returns a tile for reading.

**computeTile(int, int)** - Method in class javax.media.jai.WarpOpImage  
Computes a tile.

**computeTile(int, int)** - Method in class javax.media.jai.ScaleOpImage  
Computes a tile.

**computeTile(int, int)** - Method in class javax.media.jai.AreaOpImage  
Computes a tile.

**computeTile(int, int)** - Method in class javax.media.jai.UntiledOpImage  
Computes a tile.

**computeType** - Variable in class javax.media.jai.NullOpImage

**concatenate(AffineTransform)** - Method in class javax.media.jai.PerspectiveTransform  
Post-concatenates a given AffineTransform to this transform.

**concatenate(PerspectiveTransform)** - Method in class javax.media.jai.PerspectiveTransform  
Post-concatenates a given PerspectiveTransform to this transform.

**ConjugateDescriptor** - class javax.media.jai.operator.ConjugateDescriptor.  
An OperationDescriptor describing the "Conjugate" operation.

**ConjugateDescriptor()** - Constructor for class javax.media.jai.operator.ConjugateDescriptor  
Constructor.

**ConjugatePropertyGenerator** - class javax.media.jai.operator.ConjugatePropertyGenerator.  
This property generator computes the properties for the operation "Conjugate" dynamically.

**ConjugatePropertyGenerator()** - Constructor for class javax.media.jai.operator.ConjugatePropertyGenerator  
Constructor.

**ConstantDescriptor** - class javax.media.jai.operator.ConstantDescriptor.  
An OperationDescriptor describing the "Constant" operation.

**ConstantDescriptor()** - Constructor for class javax.media.jai.operator.ConstantDescriptor  
Constructor.

**constants** - Variable in class javax.media.jai.BorderExtenderConstant

**contains(double, double)** - Method in class javax.media.jai.ROI  
Returns true if the ROI contain the point (x, y).

**contains(double, double)** - Method in class javax.media.jai.ROIShape  
Returns true if the mask contains the point (x, y).

**contains(double, double, double, double)** - Method in class javax.media.jai.ROI  
Returns true if a given rectangle (x, y, w, h) is entirely included within the ROI.

**contains(double, double, double, double)** - Method in class javax.media.jai.ROIShape  
Returns true if a given rectangle (x, y, w, h) is entirely included within the mask.

**contains(int, int)** - Method in class javax.media.jai.ROI  
Returns true if the ROI contains the point (x, y).

**contains(int, int)** - Method in class javax.media.jai.ROIShape  
Returns true if the mask contains the point (x, y).

**contains(int, int, int, int)** - Method in class javax.media.jai.ROI  
Returns true if a given rectangle (x, y, w, h) is entirely included within the ROI.

**contains(int, int, int, int)** - Method in class javax.media.jai.ROIShape  
Returns true if a given rectangle (x, y, w, h) is entirely included within the mask.

**contains(Object)** - Method in class javax.media.jai.CollectionImage  
Returns true if this collection contains the specified object.

**contains(Object)** - Method in class javax.media.jai.CollectionOp  
Returns true if this collection contains the specified object.

**contains(Point)** - Method in class javax.media.jai.ROI  
Returns true if the ROI contains a given Point.

**contains(Point)** - Method in class javax.media.jai.ROIShape  
Returns true if the mask contains a given Point.

**contains(Point2D)** - Method in class javax.media.jai.ROI  
Returns true if the ROI contains a given Point2D.

**contains(Point2D)** - Method in class javax.media.jai.ROIShape  
Returns true if the mask contains a given Point2D.

**contains(Rectangle)** - Method in class javax.media.jai.ROI  
Returns true if a given Rectangle is entirely included within the ROI.

**contains(Rectangle)** - Method in class javax.media.jai.ROIShape  
Returns true if a given Rectangle is entirely included within the mask.

**contains(Rectangle2D)** - Method in class javax.media.jai.ROI  
Returns true if a given Rectangle2D is entirely included within the ROI.

**contains(Rectangle2D)** - Method in class javax.media.jai.ROIShape  
Returns true if a given Rectangle2D is entirely included within the mask.

**containsAll(Collection)** - Method in class javax.media.jai.CollectionImage  
Returns true if this collection contains all of the elements in the specified collection.

**containsAll(Collection)** - Method in class javax.media.jai.CollectionOp  
Returns true if this collection contains all of the elements in the specified collection.

**ConvolveDescriptor** - class javax.media.jai.operator.ConvolveDescriptor.  
An OperationDescriptor describing the "Convolve" operation.

**ConvolveDescriptor()** - Constructor for class javax.media.jai.operator.ConvolveDescriptor  
Constructor.

**coordinate** - Variable in class javax.media.jai.CoordinateImage  
The coordinate associated with the image.

**CoordinateImage** - class javax.media.jai.CoordinateImage.  
A class representing an image that is associated with a coordinate.

**CoordinateImage(PlanarImage, Object)** - Constructor for class javax.media.jai.CoordinateImage  
Constructor.

**COPIED** - Static variable in class javax.media.jai.RasterFormatTag

**COPIED** - Static variable in class javax.media.jai.RasterAccessor  
Flag indicating data is a copy of the raster's data.

**COPY\_MASK** - Static variable in class javax.media.jai.RasterFormatTag

**COPY\_MASK** - Static variable in class javax.media.jai.RasterAccessor  
The bits of a FormatTag associated with how dataArrays are obtained.

**COPY\_MASK\_SHIFT** - Static variable in class javax.media.jai.RasterAccessor  
Value indicating how far COPY\_MASK info is shifted to avoid interfering with the data type info.

**COPY\_MASK\_SIZE** - Static variable in class javax.media.jai.RasterAccessor

**copyArea(int, int, int, int, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**copyArea(int, int, int, int, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**copyArea(int, int, int, int, int, int)** - Method in class javax.media.jai.RenderableGraphics

**copyData()** - Method in class javax.media.jai.PlanarImage  
Copies the entire image into a single raster.

**copyData()** - Method in class javax.media.jai.RenderedOp  
Renders the node if it has not already been rendered, and copies and returns the entire rendered image into a single raster.

**copyData(WritableRaster)** - Method in class javax.media.jai.PlanarImage  
Copies an arbitrary rectangular region of this image's pixel data into a caller-supplied WritableRaster.

**copyData(WritableRaster)** - Method in class javax.media.jai.RenderedOp  
Renders the node if it has not already been rendered, and copies a specified rectangle of the rendered image into the given WritableRaster.

**copyData(WritableRaster)** - Method in class javax.media.jai.RemoteImage  
Returns an arbitrary rectangular region of the RemoteImage in a user-supplied WritableRaster.

**copyData(WritableRaster)** - Method in class javax.media.jai.RenderedImageAdapter  
Forwards call to the true source.

**copyDataToRaster()** - Method in class javax.media.jai.RasterAccessor  
Copies data back into the RasterAccessor's raster.

**copyExtendedData(WritableRaster, BorderExtender)** - Method in class javax.media.jai.PlanarImage  
Copies an arbitrary rectangular region of the RenderedImage into a caller-supplied WritableRaster.

**copyInDegree** - Variable in class javax.media.jai.PartialOrderNode  
Copy of the inDegree of the node.

**copyPropertyFromSource(String, int)** - Method in class javax.media.jai.PropertySourceImpl

**copyPropertyFromSource(String, String, int)** - Method in class javax.media.jai.OperationRegistry  
Forces a property to be copied from the specified source image by RenderedOp nodes performing a particular operation.

**CopyPropertyGenerator** - class javax.media.jai.CopyPropertyGenerator.  
Copy properties from a PlanarImage rendering.

**CopyPropertyGenerator(PlanarImage)** - Constructor for class javax.media.jai.CopyPropertyGenerator

**copyState(Graphics2D)** - Method in class javax.media.jai.TiledImageGraphics  
Copy the graphics state of the current object to a Graphics2D object.

**count** - Variable in class com.sun.media.jai.codec.TIFFField  
The number of data items present in the field.

**countPixels(Raster, ROI, int, int, int, int)** - Method in class javax.media.jai.Histogram  
Adds the pixels of a Raster that lie within a given region of interest (ROI) to the histogram.

**countPixelsByte(RasterAccessor, Rectangle, int, int)** - Method in class javax.media.jai.Histogram

**countPixelsDouble(RasterAccessor, Rectangle, int, int)** - Method in class javax.media.jai.Histogram

**countPixelsFloat(RasterAccessor, Rectangle, int, int)** - Method in class javax.media.jai.Histogram

**countPixelsInt(RasterAccessor, Rectangle, int, int)** - Method in class javax.media.jai.Histogram

**countPixelsShort(RasterAccessor, Rectangle, int, int)** - Method in class javax.media.jai.Histogram

**countPixelsUShort(RasterAccessor, Rectangle, int, int)** - Method in class javax.media.jai.Histogram

**create()** - Method in class javax.media.jai.GraphicsJAI  
Creates a new GraphicsJAI object that is a copy of this GraphicsJAI object.

**create()** - Method in class javax.media.jai.TiledImageGraphics

**create()** - Method in class javax.media.jai.RenderableGraphics

**create(ParameterBlock, RenderingHints)** - Method in interface javax.media.jai.CollectionImageFactory  
Creates a CollectionImage that represents the result of an operation (or chain of operations) for a given ParameterBlock and RenderingHints.

**create(Raster, Rectangle)** - Static method in class javax.media.jai.iterator.RandomIterFactory  
Constructs and returns an instance of RandomIter suitable for iterating over the given bounding rectangle within the given Raster source.

**create(Raster, Rectangle)** - Static method in class javax.media.jai.iterator.RectIterFactory  
Constructs and returns an instance of RectIter suitable for iterating over the given bounding rectangle within the given Raster source.

**create(Raster, Rectangle)** - Static method in class javax.media.jai.iterator.RookIterFactory  
Constructs and returns an instance of RookIter suitable for iterating over the given bounding rectangle within the given Raster source.

**create(RenderedImage, Rectangle)** - Static method in class javax.media.jai.iterator.RandomIterFactory  
Constructs and returns an instance of RandomIter suitable for iterating over the given bounding rectangle within the given RenderedImage source.

**create(RenderedImage, Rectangle)** - Static method in class javax.media.jai.iterator.RectIterFactory  
Constructs and returns an instance of RectIter suitable for iterating over the given bounding rectangle within the given RenderedImage source.

**create(RenderedImage, Rectangle)** - Static method in class javax.media.jai.iterator.RookIterFactory  
Constructs and returns an instance of RookIter suitable for iterating over the given bounding rectangle within the given RenderedImage source.

**create(String, Collection)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 Collection source.

**create(String, int, int, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 2 int parameters and one object parameter

**create(String, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 object parameter.

**create(String, Object, int)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 object parameter and 1 int parameter

**create(String, Object, int, Object, int)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 2 object and 2 int parameters.

**create(String, Object, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 2 object parameters.

**create(String, Object, Object, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 3 object parameters.

**create(String, Object, Object, Object, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 4 object parameters.

**create(String, ParameterBlock)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp with null rendering hints.

**create(String, ParameterBlock, RenderingHints)** - Method in class javax.media.jai.OperationRegistry  
Constructs a PlanarImage (usually a RenderedOp) representing the results of applying a given operation to a particular ParameterBlock and rendering hints.

**create(String, ParameterBlock, RenderingHints)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp which represents the named operation, using the source(s) and/or parameter(s) specified in the ParameterBlock, and applying the specified hints to the destination.

**create(String, RenderedImage)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source.

**create(String, RenderedImage, float, float, float, float, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source, 4 float parameters and one object parameter.

**create(String, RenderedImage, float, float, float, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source, 3 float and 1 object parameters.

**create(String, RenderedImage, float, float, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source, 2 float and 1 object parameters.

**create(String, RenderedImage, float, int, float, float, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source, 3 float parameters, 1 int parameter and 1 object parameter.

**create(String, RenderedImage, int)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source and 1 int parameter.

**create(String, RenderedImage, int, int, int, int)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source and 4 int parameters.

**create(String, RenderedImage, int, int, int, int, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source, 5 int parameters and 1 object parameter.

**create(String, RenderedImage, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source and 1 object parameter.

**create(String, RenderedImage, Object, float)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source, 1 object and 1 float parameter.

**create(String, RenderedImage, Object, int, int)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source, 1 object and 2 int parameters.

**create(String, RenderedImage, Object, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source and 2 object parameters.

**create(String, RenderedImage, Object, Object, int, int)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source and 2 object parameters and 2 in parameters

**create(String, RenderedImage, Object, Object, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source and 3 object parameters.

**create(String, RenderedImage, Object, Object, Object, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source and 4 object parameters.

**create(String, RenderedImage, Object, Object, Object, Object, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source and 5 object parameters.

**create(String, RenderedImage, Object, Object, Object, Object, Object, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 1 RenderedImage source and 6 object parameters.

**create(String, RenderedImage, RenderedImage)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 2 RenderedImage sources.

**create(String, RenderedImage, RenderedImage, Object, Object, Object, Object)** - Static method in class javax.media.jai.JAI  
Creates a RenderedOp that takes 2 RenderedImage sources and 4 object parameters.

**createAdjoint()** - Method in class javax.media.jai.PerspectiveTransform  
Returns a new PerspectiveTransform that is the adjoint, of the current transform.

**createBanded(int, int, int, int, int, int, int, int[], int[])** - Static method in class javax.media.jai.TiledImage  
Returns a TiledImage making use of an banded SampleModel with a given layout, number of bands, and data type.

**createBandedRaster(DataBuffer, int, int, int, int[], int[], Point)** - Static method in class javax.media.jai.RasterFactory  
Creates a WritableRaster based on a ComponentSampleModel with the specified DataBuffer, width, height, scanline stride, bank indices, and band offsets.

**createBandedRaster(int, int, int, int, int[], int[], Point)** - Static method in class javax.media.jai.RasterFactory  
Creates a WritableRaster based on a ComponentSampleModel with the specified data type, width, height, scanline stride, bank indices and band offsets.

**createBandedRaster(int, int, int, int, Point)** - Static method in class javax.media.jai.RasterFactory  
Creates a WritableRaster based on a ComponentSampleModel with the specified data type, width, height, and number of bands.

**createBandedSampleModel(int, int, int, int)** - Static method in class javax.media.jai.RasterFactory  
Creates a banded SampleModel with a given data type, width, height, and number of bands.

**createBandedSampleModel(int, int, int, int, int[], int[])** - Static method in class javax.media.jai.RasterFactory  
Creates a banded SampleModel with a given data type, width, height, number of bands, bank indices, and band offsets.

**createCollection()** - Method in class javax.media.jai.CollectionOp  
Creates a collection rendering if none exists.

**createCollection(String, ParameterBlock)** - Static method in class javax.media.jai.JAI  
Creates a Collection with null rendering hints.

**createCollection(String, ParameterBlock, RenderingHints)** - Method in class javax.media.jai.OperationRegistry  
Constructs a CollectionImage (usually a CollectionOp) representing the results of applying a given operation to a particular ParameterBlock and rendering hints.

**createCollection(String, ParameterBlock, RenderingHints)** - Static method in class javax.media.jai.JAI  
Creates a Collection which represents the named operation, using the source(s) and/or parameter(s) specified in the ParameterBlock, and applying the specified hints to the destination.

**createCollectionNS(String, ParameterBlock, RenderingHints)** - Method in class javax.media.jai.JAI  
Creates a Collection which represents the named operation, using the source(s) and/or parameter(s) specified in the ParameterBlock, and applying the specified hints to the destination.

**createColorCube(int, int[])** - Static method in class javax.media.jai.ColorCube  
Returns a multi-banded ColorCube of a specified data type with zero offset for all bands.

**createColorCube(int, int, int[])** - Static method in class javax.media.jai.ColorCube  
Returns a multi-banded ColorCube of a specified data type.

**createColorCubeByte(int, int[])** - Static method in class javax.media.jai.ColorCube  
Returns a multi-banded byte ColorCube with an index offset common to all bands.

**createColorCubeDouble(int, int[])** - Static method in class javax.media.jai.ColorCube  
Returns a multi-banded double ColorCube with an index offset common to all bands.

**createColorCubeFloat(int, int[])** - Static method in class javax.media.jai.ColorCube  
Returns a multi-banded float ColorCube with an index offset common to all bands.

**createColorCubeInt(int, int[])** - Static method in class javax.media.jai.ColorCube  
Returns a multi-banded int ColorCube with an index offset common to all bands.

**createColorCubeShort(int, int[])** - Static method in class javax.media.jai.ColorCube  
Returns a multi-banded short ColorCube with an index offset common to all bands.

**createColorCubeUShort(int, int[])** - Static method in class javax.media.jai.ColorCube  
Returns a multi-banded unsigned short ColorCube with an index offset common to all bands.

**createColorModel(SampleModel)** - Static method in class javax.media.jai.PlanarImage  
Creates a ColorModel that may be used with the specified SampleModel.

**createCompatibleSampleModel(int, int)** - Method in class javax.media.jai.FloatDoubleColorModel  
Creates a SampleModel with the specified width and height that has a data layout compatible with this ColorModel.

**createCompatibleSampleModel(int, int)** - Method in class javax.media.jai.ComponentSampleModelJAI  
Creates a new ComponentSampleModel with the specified width and height.

**createCompatibleWritableRaster(int, int)** - Method in class javax.media.jai.FloatDoubleColorModel  
Creates a WritableRaster with the specified width and height, that has a data layout (SampleModel) compatible with this ColorModel.

**createComponentColorModel(int, ColorSpace, boolean, boolean, int)** - Static method in class javax.media.jai.RasterFactory  
Creates a component-based ColorModel with a given data type, color space, and transparency type.

**createComponentColorModel(SampleModel)** - Static method in class com.sun.media.jai.codec.ImageCodec  
A convenience method to create an instance of ComponentColorModel suitable for use with the given SampleModel.

**createComponentSampleModel(SampleModel, int, int, int, int)** - Static method in class javax.media.jai.RasterFactory  
Creates a component SampleModel with a given data type, width, height, and number of bands that is "compatible" with a given SampleModel.

**createDataArray(int, int, int[])** - Static method in class javax.media.jai.ColorCube  
Constructs a two-dimensional array of the requested data type which represents the contents of a color cube.

**createDataArrayByte(int, int[])** - Static method in class javax.media.jai.ColorCube  
Constructs a two-dimensional array of byte data which represent the contents of a color cube.

**createDataArrayDouble(int, int[])** - Static method in class javax.media.jai.ColorCube  
Constructs a two-dimensional array of double data which represent the contents of a color cube.

**createDataArrayFloat(int, int[])** - Static method in class javax.media.jai.ColorCube  
Constructs a two-dimensional array of float data which represent the contents of a color cube.

**createDataArrayInt(int, int[])** - Static method in class javax.media.jai.ColorCube  
Constructs a two-dimensional array of int data which represent the contents of a color cube.

**createDataArrayShort(int, int[])** - Static method in class javax.media.jai.ColorCube  
Constructs a two-dimensional array of short data which represent the contents of a color cube.

**createDataArrayUShort(int, int[])** - Static method in class javax.media.jai.ColorCube  
Constructs a two-dimensional array of unsigned short data which represent the contents of a color cube.

**createDataBuffer()** - Method in class javax.media.jai.ComponentSampleModelJAI  
Creates a DataBuffer that corresponds to this ComponentSampleModel.

**createDefaultRendering()** - Method in class javax.media.jai.RenderableOp  
Returns a RenderedImage instance of this image equivalent to what would be obtained by invoking createRendering() with the identity transform, an area of interest equal to the image bounds, and no rendering hints.

**createDefaultRendering()** - Method in class javax.media.jai.RenderableImageAdapter  
Gets a RenderedImage instance of this image with a default width and height in pixels.

**createDefaultRendering()** - Method in class javax.media.jai.MultiResolutionRenderableImage  
Returns the full resolution source RenderedImage with no rendering hints.

**createDefaultRendering()** - Method in class javax.media.jai.RenderableGraphics

**createFormatter(String)** - Method in class javax.media.jai.OperationDescriptorImpl  
Creates a MessageFormat object and set the Locale to default.

**createGraphics()** - Method in class javax.media.jai.TiledImage  
Creates a Graphics2D object that can be used to paint text and graphics onto the TiledImage.

**createGraphicsJAI(Graphics2D, Component)** - Static method in class javax.media.jai.GraphicsJAI  
Returns an instance of GraphicsJAI suitable for rendering to the given Component via the given Graphics2D instance.

**createGrayIndexColorModel(SampleModel, boolean)** - Static method in class com.sun.media.jai.codec.ImageCodec  
A convenience methods to create an instance of IndexColorModel suitable for the given 1-banded SampleModel.

**createImageDecoder(File, ImageDecodeParam)** - Method in class com.sun.media.jai.codec.ImageCodec  
Returns an implementation of the ImageDecoder interface appropriate for that codec.

**createImageDecoder(InputStream, ImageDecodeParam)** - Method in class com.sun.media.jai.codec.ImageCodec  
Returns an implementation of the ImageDecoder interface appropriate for that codec.

**createImageDecoder(SeekableStream, ImageDecodeParam)** - Method in class com.sun.media.jai.codec.ImageCodec  
In a concrete subclass of ImageCodec, returns an implementation of the ImageDecoder interface appropriate for that codec.

**createImageDecoder(String, File, ImageDecodeParam)** - Static method in class com.sun.media.jai.codec.ImageCodec  
Returns an ImageDecoder object suitable for decoding from the supplied File, using the supplied ImageDecodeParam object.

**createImageDecoder(String, InputStream, ImageDecodeParam)** - Static method in class com.sun.media.jai.codec.ImageCodec  
Returns an ImageDecoder object suitable for decoding from the supplied InputStream, using the supplied ImageDecodeParam object.

**createImageDecoder(String, SeekableStream, ImageDecodeParam)** - Static method in class com.sun.media.jai.codec.ImageCodec  
Returns an ImageDecoder object suitable for decoding from the supplied SeekableStream, using the supplied ImageDecodeParam object.

**createImageEncoder(OutputStream, ImageEncodeParam)** - Method in class com.sun.media.jai.codec.ImageCodec  
In a concrete subclass of ImageCodec, returns an implementation of the ImageEncoder interface appropriate for that codec.

**createImageEncoder(String, OutputStream, ImageEncodeParam)** - Static method in class com.sun.media.jai.codec.ImageCodec  
Returns an ImageEncoder object suitable for encoding to the supplied OutputStream, using the supplied ImageEncoderParam object.

**createInstance()** - Method in class javax.media.jai.RenderedOp  
Instantiate a PlanarImage that computes the result of this RenderedOp.

**createInstance()** - Method in class javax.media.jai.CollectionOp  
Instantiates a collection operator that computes the result of this CollectionOp.

**createInstance(boolean)** - Method in class javax.media.jai.RenderedOp  
This method performs the actions described by the documentation of createInstance() optionally freezing the image chain as a function of the parameter.

**createInstance(boolean)** - Method in class javax.media.jai.CollectionOp  
This method performs the actions described by the documentation of createInstance() optionally freezing the image chain as a function of the parameter.

**createInstance(int)** - Static method in class javax.media.jai.BorderExtender  
Returns an instance of BorderExtender that implements a given extension policy.

**createInterleaved(int, int, int, int, int, int, int, int, int, int[])** - Static method in class javax.media.jai.TiledImage  
Returns a TiledImage making use of an interleaved SampleModel with a given layout, number of bands, and data type.

**createInterleavedRaster(DataBuffer, int, int, int, int, int[], Point)** - Static method in class javax.media.jai.RasterFactory  
Creates a WritableRaster based on a PixelInterleavedSampleModel with the specified DataBuffer, width, height, scanline stride, pixel stride, and band offsets.

**createInterleavedRaster(int, int, int, int, int, int[], Point)** - Static method in class javax.media.jai.RasterFactory  
Creates a WritableRaster based on a PixelInterleavedSampleModel with the specified data type, width, height, scanline stride, pixel stride, and band offsets.

**createInterleavedRaster(int, int, int, int, Point)** - Static method in class javax.media.jai.RasterFactory  
Creates a WritableRaster based on a PixelInterleavedSampleModel with the specified data type, width, height, and number of bands.

**createInverse()** - Method in class javax.media.jai.PerspectiveTransform  
Returns a new PerspectiveTransform that is the inverse of the current transform.

**createLocalProperties()** - Method in class javax.media.jai.RenderedOp  
Initialize the localProperties Hashtable if needed.

**createLocalProperties()** - Method in class javax.media.jai.RenderableOp  
Initialize the localProperties Hashtable if needed.

**createNS(String, ParameterBlock, RenderingHints)** - Method in class javax.media.jai.JAI  
Creates a RenderedOp which represents the named operation, using the source(s) and/or parameter(s) specified in the ParameterBlock, and applying the specified hints to the destination.

**createPackedRaster(DataBuffer, int, int, int, int[], Point)** - Static method in class javax.media.jai.RasterFactory  
Creates a WritableRaster based on a SinglePixelPackedSampleModel with the specified DataBuffer, width, height, scanline stride, and band masks.

**createPackedRaster(DataBuffer, int, int, int, Point)** - Static method in class javax.media.jai.RasterFactory  
Creates a WritableRaster based on a MultiPixelPackedSampleModel with the specified DataBuffer, width, height, and bits per pixel.

**createPackedRaster(int, int, int, int[], Point)** - Static method in class `javax.media.jai.RasterFactory`  
Creates a `WritableRaster` based on a `SinglePixelPackedSampleModel` with the specified data type, width, height, and band masks.

**createPackedRaster(int, int, int, int, Point)** - Static method in class `javax.media.jai.RasterFactory`  
Creates a `WritableRaster` based on a packed `SampleModel` with the specified data type, width, height, number of bands, and bits per band.

**createPixelInterleavedSampleModel(int, int, int, int)** - Static method in class `javax.media.jai.RasterFactory`  
Creates a pixel interleaved `SampleModel` with a given data type, width, height, and number of bands.

**createPixelInterleavedSampleModel(int, int, int, int, int, int, int[])** - Static method in class `javax.media.jai.RasterFactory`  
Creates a pixel interleaved `SampleModel` with a given data type, width, height, pixel and scanline strides, and band offsets.

**createPropertySource()** - Method in class `javax.media.jai.RenderedOp`  
Creates a `PropertySource` if none exists.

**createPropertySource()** - Method in class `javax.media.jai.RenderableOp`  
Creates a `PropertySource` if none exists.

**createRaster(SampleModel, DataBuffer, Point)** - Static method in class `javax.media.jai.RasterFactory`  
Creates a `WritableRaster` with the specified `SampleModel` and `DataBuffer`.

**createRenderable(String, ParameterBlock)** - Method in class `javax.media.jai.OperationRegistry`  
Constructs the CRIF to be used to instantiate the operation.

**createRenderable(String, ParameterBlock)** - Static method in class `javax.media.jai.JAI`  
Creates a `RenderableOp` that represents the named operation, using the source(s) and/or parameter(s) specified in the `ParameterBlock`.

**createRenderableCollection(String, ParameterBlock)** - Static method in class `javax.media.jai.JAI`  
Creates a `Collection` which represents the named operation, using the source(s) and/or parameter(s) specified in the `ParameterBlock`.

**createRenderableCollectionNS(String, ParameterBlock)** - Method in class `javax.media.jai.JAI`  
Creates a `Collection` which represents the named operation, using the source(s) and/or parameter(s) specified in the `ParameterBlock`.

**createRenderableNS(String, ParameterBlock)** - Method in class `javax.media.jai.JAI`  
Creates a `RenderableOp` that represents the named operation, using the source(s) and/or parameter(s) specified in the `ParameterBlock`.

**createRendering()** - Method in class `javax.media.jai.RenderedOp`  
Creates an `RenderedImage` rendering if none exists.

**createRendering(RenderContext)** - Method in class `javax.media.jai.RenderableOp`  
Gets a `RenderedImage` that represented a rendering of this image using a given `RenderContext`.

**createRendering(RenderContext)** - Method in class `javax.media.jai.RenderableImageAdapter`  
Gets a `RenderedImage` instance of this image from a `RenderContext`.

**createRendering(RenderContext)** - Method in class `javax.media.jai.MultiResolutionRenderableImage`  
Returns a rendering based on a `RenderContext`.

**createRendering(RenderContext)** - Method in class `javax.media.jai.RenderableGraphics`  
Creates a `RenderedImage` that represents a rendering of this image using a given `RenderContext`.

**createScaledRendering(int, int, RenderingHints)** - Method in class `javax.media.jai.RenderableOp`  
Gets a `RenderedImage` instance of this image with width `w`, and height `h` in pixels.

**createScaledRendering(int, int, RenderingHints)** - Method in class `javax.media.jai.RenderableImageAdapter`  
Gets a `RenderedImage` instance of this image with width `w`, and height `h` in pixels.

**createScaledRendering(int, int, RenderingHints)** - Method in class `javax.media.jai.MultiResolutionRenderableImage`  
Returns a rendering with a given width, height, and rendering hints.

**createScaledRendering(int, int, RenderingHints)** - Method in class `javax.media.jai.RenderableGraphics`

**createSnapshot()** - Method in class `javax.media.jai.PlanarImage`  
Creates a snapshot, that is, a virtual copy of the image's current contents.

**createSnapshot()** - Method in class `javax.media.jai.SnapshotImage`  
Creates a snapshot of this image.

**createStatistics(String)** - Method in class `javax.media.jai.StatisticsOpImage`  
Returns an object that will be used to gather the named statistic.

**createSubsetSampleModel(int[])** - Method in class `javax.media.jai.ComponentSampleModelJAI`  
This creates a new `ComponentSampleModel` with a subset of the bands of this `ComponentSampleModel`.

**createSynthProperties()** - Method in class `javax.media.jai.RenderedOp`  
Initialize the `synthProperties` `Hashtable` if needed.

**createTile(int, int)** - Method in class `javax.media.jai.TiledImage`  
Forces the requested tile to be computed if has not already been so and if a source is available.

**createTileCache()** - Static method in class `javax.media.jai.JAI`  
Constructs a `TileCache` with the default tile capacity in tiles and memory capacity in bytes.

**createTileCache(int, long)** - Static method in class `javax.media.jai.JAI`  
Constructs a `TileCache` with the given tile capacity in tiles and memory capacity in bytes.

**createTileCopy(int, int)** - Method in class `javax.media.jai.SnapshotImage`  
Creates and returns a `Raster` copy of a given source tile.

**createTiledImage(RenderingHints, Rectangle)** - Method in class javax.media.jai.RenderableGraphics  
Create a TiledImage to be used as the canvas.

**createVolatilePropertyVector()** - Method in class javax.media.jai.RenderedOp  
Creates a volatile property info Vector if none exists.

**createVolatilePropertyVector()** - Method in class javax.media.jai.RenderableOp  
Creates a volatile property info Vector if none exists.

**createWarp(float[], int, float[], int, int, float, float, float, float, int)** - Static method in class javax.media.jai.WarpPolynomial  
Returns an instance of WarpPolynomial or its subclasses that approximately maps the given scaled destination image coordinates into the given scaled source image coordinates.

**createWritable(WritableRaster, Rectangle)** - Static method in class javax.media.jai.iterator.RandomIterFactory  
Constructs and returns an instance of WritableRandomIter suitable for iterating over the given bounding rectangle within the given WritableRaster source.

**createWritable(WritableRaster, Rectangle)** - Static method in class javax.media.jai.iterator.RectIterFactory  
Constructs and returns an instance of WritableRectIter suitable for iterating over the given bounding rectangle within the given WritableRaster source.

**createWritable(WritableRaster, Rectangle)** - Static method in class javax.media.jai.iterator.RookIterFactory  
Constructs and returns an instance of WritableRookIter suitable for iterating over the given bounding rectangle within the given WritableRaster source.

**createWritable(WritableRenderedImage, Rectangle)** - Static method in class javax.media.jai.iterator.RandomIterFactory  
Constructs and returns an instance of WritableRandomIter suitable for iterating over the given bounding rectangle within the given WritableRenderedImage source.

**createWritable(WritableRenderedImage, Rectangle)** - Static method in class javax.media.jai.iterator.RectIterFactory  
Constructs and returns an instance of WritableRectIter suitable for iterating over the given bounding rectangle within the given WritableRenderedImage source.

**createWritable(WritableRenderedImage, Rectangle)** - Static method in class javax.media.jai.iterator.RookIterFactory  
Constructs and returns an instance of WritableRookIter suitable for iterating over the given bounding rectangle within the given WritableRenderedImage source.

**createWritableChild(WritableRaster, int, int, int, int, int, int, int[])** - Static method in class javax.media.jai.RasterFactory  
Returns a new WritableRaster which shares all or part of the supplied WritableRaster's DataBuffer.

**createWritableRaster(SampleModel, DataBuffer, Point)** - Static method in class javax.media.jai.RasterFactory  
Creates a WritableRaster with the specified SampleModel and DataBuffer.

**createWritableRaster(SampleModel, Point)** - Static method in class javax.media.jai.RasterFactory  
Creates a WritableRaster with the specified SampleModel.

**crif** - Variable in class javax.media.jai.RenderableOp

**crifs** - Variable in class javax.media.jai.OperationRegistry  
Hashtable of all the crifs, hashed by the operationName to which they belong.

**crifTable** - Variable in class javax.media.jai.RegistryInitData

**CropDescriptor** - class javax.media.jai.operator.CropDescriptor.  
An OperationDescriptor describing the "Crop" operation.

**CropDescriptor()** - Constructor for class javax.media.jai.operator.CropDescriptor  
Constructor.

**currentImage** - Variable in class javax.media.jai.ImageMIPMap  
The image at the current resolution level.

**currentIndex** - Variable in class javax.media.jai.IntegerSequence  
The current element of the iteration.

**currentLevel** - Variable in class javax.media.jai.ImageMIPMap  
The current resolution level.

**currentPage** - Variable in class com.sun.media.jai.codec.FileSeekableStream

---

## D

**data** - Variable in class javax.media.jai.DataBufferDouble  
A reference to the default data bank.

**data** - Variable in class javax.media.jai.LookupTableJAI  
The table data.

**data** - Variable in class javax.media.jai.DataBufferFloat  
A reference to the default data bank.

**data** - Variable in class javax.media.jai.KernelJAI  
The kernel data in row-major format.

**data** - Variable in class com.sun.media.jai.codec.MemoryCacheSeekableStream  
A Vector of source sectors.

**data** - Variable in class com.sun.media.jai.codec.TIFFField  
The field data.

**DataBufferDouble** - class javax.media.jai.DataBufferDouble.  
 An extension of `DataBuffer` that stores data internally in double form.

**DataBufferDouble(double[[]], int)** - Constructor for class javax.media.jai.DataBufferDouble  
 Constructs a double-based `DataBuffer` with the specified data arrays.

**DataBufferDouble(double[[]], int, int[])** - Constructor for class javax.media.jai.DataBufferDouble  
 Constructs a double-based `DataBuffer` with the specified data arrays, size, and per-bank offsets.

**DataBufferDouble(double[], int)** - Constructor for class javax.media.jai.DataBufferDouble  
 Constructs a double-based `DataBuffer` with the specified data array.

**DataBufferDouble(double[], int, int)** - Constructor for class javax.media.jai.DataBufferDouble  
 Constructs a double-based `DataBuffer` with the specified data array.

**DataBufferDouble(int)** - Constructor for class javax.media.jai.DataBufferDouble  
 Constructs a double-based `DataBuffer` with a specified size.

**DataBufferDouble(int, int)** - Constructor for class javax.media.jai.DataBufferDouble  
 Constructs a double-based `DataBuffer` with a specified number of banks, all of which are of a specified size.

**DataBufferFloat** - class javax.media.jai.DataBufferFloat.  
 An extension of `DataBuffer` that stores data internally in float form.

**DataBufferFloat(float[[]], int)** - Constructor for class javax.media.jai.DataBufferFloat  
 Constructs a float-based `DataBuffer` with the specified data arrays.

**DataBufferFloat(float[[]], int, int[])** - Constructor for class javax.media.jai.DataBufferFloat  
 Constructs a float-based `DataBuffer` with the specified data arrays, size, and per-bank offsets.

**DataBufferFloat(float[], int)** - Constructor for class javax.media.jai.DataBufferFloat  
 Constructs a float-based `DataBuffer` with the specified data array.

**DataBufferFloat(float[], int, int)** - Constructor for class javax.media.jai.DataBufferFloat  
 Constructs a float-based `DataBuffer` with the specified data array.

**DataBufferFloat(int)** - Constructor for class javax.media.jai.DataBufferFloat  
 Constructs a float-based `DataBuffer` with a specified size.

**DataBufferFloat(int, int)** - Constructor for class javax.media.jai.DataBufferFloat  
 Constructs a float-based `DataBuffer` with a specified number of banks, all of which are of a specified size.

**dataH** - Variable in class javax.media.jai.KernelJAI  
 The horizontal data for a separable kernel

**dataHd** - Variable in class javax.media.jai.InterpolationTable  
 The horizontal coefficient data in double format.

**dataHelper(int)** - Static method in class javax.media.jai.InterpolationBicubic2

**dataHelper(int)** - Static method in class javax.media.jai.InterpolationBicubic

**dataHf** - Variable in class javax.media.jai.InterpolationTable  
 The horizontal coefficient data in floating-point format.

**dataHi** - Variable in class javax.media.jai.InterpolationTable  
 The horizontal coefficient data in fixed-point format.

**dataType** - Variable in class javax.media.jai.ColorCube  
 The data type cached to accelerate `findNearestEntry()`.

**DATATYPE\_MASK** - Static variable in class javax.media.jai.RasterAccessor  
 The bits of a `FormatTagID` associated with pixel datatype.

**dataV** - Variable in class javax.media.jai.KernelJAI  
 The vertical data for a separable kernel

**dataVd** - Variable in class javax.media.jai.InterpolationTable  
 The vertical coefficient data in double format.

**dataVf** - Variable in class javax.media.jai.InterpolationTable  
 The vertical coefficient data in floating-point format.

**dataVi** - Variable in class javax.media.jai.InterpolationTable  
 The vertical coefficient data in fixed-point format.

**DCTDescriptor** - class javax.media.jai.operator.DCTDescriptor.  
 An `OperationDescriptor` describing the "DCT" operation.

**DCTDescriptor()** - Constructor for class javax.media.jai.operator.DCTDescriptor  
 Constructor.

**decode16BitsTo8Bits(int)** - Method in class com.sun.media.jai.codec.TIFFDecodeParam  
 Returns an unsigned 8 bit value computed by dithering the unsigned 16 bit value.

**decodeAsRaster()** - Method in class com.sun.media.jai.codec.ImageDecoderImpl  
 Returns a `Raster` that contains the decoded contents of the `SeekableStream` associated with this `ImageDecoder`.

**decodeAsRaster()** - Method in interface com.sun.media.jai.codec.ImageDecoder  
 Returns a `Raster` that contains the decoded contents of the `SeekableStream` associated with this `ImageDecoder`.

**decodeAsRaster(int)** - Method in class com.sun.media.jai.codec.ImageDecoderImpl  
 Returns a `Raster` that contains the decoded contents of the `SeekableStream` associated with this `ImageDecoder`.

**decodeAsRaster(int)** - Method in interface com.sun.media.jai.codec.ImageDecoder  
 Returns a `Raster` that contains the decoded contents of the `SeekableStream` associated with this `ImageDecoder`.

**decodeAsRenderedImage()** - Method in class com.sun.media.jai.codec.ImageDecoderImpl  
Returns a `RenderedImage` that contains the decoded contents of the `SeekableStream` associated with this `ImageDecoder`.

**decodeAsRenderedImage()** - Method in interface com.sun.media.jai.codec.ImageDecoder  
Returns a `RenderedImage` that contains the decoded contents of the `SeekableStream` associated with this `ImageDecoder`.

**decodeAsRenderedImage(int)** - Method in class com.sun.media.jai.codec.ImageDecoderImpl  
Returns a `RenderedImage` that contains the decoded contents of the `SeekableStream` associated with this `ImageDecoder`.

**decodeAsRenderedImage(int)** - Method in interface com.sun.media.jai.codec.ImageDecoder  
Returns a `RenderedImage` that contains the decoded contents of the `SeekableStream` associated with this `ImageDecoder`.

**decodePaletteAsShorts** - Variable in class com.sun.media.jai.codec.TIFFDecodeParam

**decodeSigned16BitsTo8Bits(short)** - Method in class com.sun.media.jai.codec.TIFFDecodeParam  
Returns an unsigned 8 bit value computed by dithering the signed 16 bit value.

**decrementCopyInDegree()** - Method in class javax.media.jai.PartialOrderNode  
Decrements the copy in-degree of a node.

**decrementInDegree()** - Method in class javax.media.jai.PartialOrderNode  
Decrements the in-degree of a node.

**DEFAULT\_CAPACITY** - Static variable in class javax.media.jai.IntegerSequence  
The default initial capacity of `iArray`.

**DEFAULT\_KERNEL\_ID** - Static variable in class javax.media.jai.operator.RenderableDescriptor

**DEFAULT\_NUM\_RETRIES** - Static variable in class javax.media.jai.RemoteImage  
The default number of retries.

**DEFAULT\_SUBSAMPLE\_BITS** - Static variable in class javax.media.jai.InterpolationBilinear

**DEFAULT\_TIMEOUT** - Static variable in class javax.media.jai.RemoteImage  
The amount of time to wait between retries.

**defaultColorModels** - Static variable in class javax.media.jai.PlanarImage

**defaultCursor** - Variable in class javax.media.jai.widget.ScrollingImagePanel  
A place to save the cursor.

**DEFAULTEXPANSION** - Static variable in class javax.media.jai.RasterAccessor  
Flag indicating `ColorModel` data should be used only in copied case

**defaultInstance** - Static variable in class javax.media.jai.JAI

**degree** - Variable in class javax.media.jai.WarpPolynomial  
The degree of the polynomial, determined by the number of coefficients supplied via the `X` and `Y` coefficients arrays.

**deleteEdge(Vector, int)** - Method in class javax.media.jai.ROIShape.PolyShape  
Delete a `PolyEdge` from the `Vector` of active edges.

**descTable** - Variable in class javax.media.jai.RegistryInitData

**DESTINATION\_ALPHA\_FIRST** - Static variable in class javax.media.jai.operator.CompositeDescriptor  
The destination image has the channel, and it is the first band.

**DESTINATION\_ALPHA\_LAST** - Static variable in class javax.media.jai.operator.CompositeDescriptor  
The destination image has the channel, and it is the last band.

**DFTDescriptor** - class javax.media.jai.operator.DFTDescriptor.  
An `OperationDescriptor` describing the "DFT" operation.

**DFTDescriptor()** - Constructor for class javax.media.jai.operator.DFTDescriptor  
Constructor.

**DFTPropertyGenerator** - class javax.media.jai.operator.DFTPropertyGenerator.  
This property generator computes the properties for the operation "DFT" dynamically.

**DFTPropertyGenerator()** - Constructor for class javax.media.jai.operator.DFTPropertyGenerator  
Constructor.

**differencec** - Variable in class javax.media.jai.ImagePyramid  
The operation chain used to differ two images.

**diffImages** - Variable in class javax.media.jai.ImagePyramid  
The saved different images.

**dimension** - Variable in class javax.media.jai.ColorCube  
The signed array of sizes used to create the `ColorCube`.

**dimensions** - Variable in class javax.media.jai.RenderableGraphics

**dimsLessOne** - Variable in class javax.media.jai.ColorCube  
An array of positive values each of whose elements is one less than the absolute value of the corresponding element of the dimension array.

**displayExponent** - Variable in class com.sun.media.jai.codec.PNGDecodeParam

**dispose()** - Method in class javax.media.jai.PlanarImage  
Provides a hint that an image will no longer be accessed from a reference in user space.

**dispose()** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**dispose()** - Method in class javax.media.jai.TiledImageGraphics

**dispose()** - Method in class javax.media.jai.SnapshotProxy  
Disposes of resources held by this proxy.

**dispose()** - Method in class javax.media.jai.Snapshot  
This image will no longer be referenced by the user.

**dispose()** - Method in class javax.media.jai.RenderableGraphics

**disposed** - Variable in class javax.media.jai.PlanarImage

**disposed** - Variable in class javax.media.jai.Snapshot  
True if dispose() has been called.

**DITHER\_MASK\_441** - Static variable in class javax.media.jai.KernelJAI  
4x4x1 mask useful for dithering 8-bit grayscale images to 1-bit images.

**DITHER\_MASK\_443** - Static variable in class javax.media.jai.KernelJAI  
4x4x3 mask useful for dithering 24-bit color images to 8-bit pseudocolor images.

**DivideByConstDescriptor** - class javax.media.jai.operator.DivideByConstDescriptor.  
An `OperationDescriptor` describing the "DivideByConst" operation.

**DivideByConstDescriptor()** - Constructor for class javax.media.jai.operator.DivideByConstDescriptor  
Constructor.

**DivideComplexDescriptor** - class javax.media.jai.operator.DivideComplexDescriptor.  
An `OperationDescriptor` describing the "DivideComplex" operation.

**DivideComplexDescriptor()** - Constructor for class javax.media.jai.operator.DivideComplexDescriptor  
Constructor.

**DivideComplexPropertyGenerator** - class javax.media.jai.operator.DivideComplexPropertyGenerator.  
This property generator computes the properties for the operation "DivideComplex" dynamically.

**DivideComplexPropertyGenerator()** - Constructor for class javax.media.jai.operator.DivideComplexPropertyGenerator  
Constructor.

**DivideDescriptor** - class javax.media.jai.operator.DivideDescriptor.  
An `OperationDescriptor` describing the "Divide" operation.

**DivideDescriptor()** - Constructor for class javax.media.jai.operator.DivideDescriptor  
Constructor.

**DivideIntoConstDescriptor** - class javax.media.jai.operator.DivideIntoConstDescriptor.  
An `OperationDescriptor` describing the "DivideIntoConst" operation.

**DivideIntoConstDescriptor()** - Constructor for class javax.media.jai.operator.DivideIntoConstDescriptor  
Constructor.

**doGraphicsOp(int, int, int, int, String, Class[], Object[])** - Method in class javax.media.jai.TiledImageGraphics  
Effect a graphics operation on the `TiledImage` by creating a `BufferedImage` for each tile in the affected region and using the corresponding `Graphics2D` to perform the equivalent operation on the tile.

**doGraphicsOp(Shape, String, Class[], Object[])** - Method in class javax.media.jai.TiledImageGraphics  
Effect a graphics operation on the `TiledImage` by creating a `BufferedImage` for each tile in the affected region and using the corresponding `Graphics2D` to perform the equivalent operation on the tile.

**done()** - Method in interface javax.media.jai.iterator.RandomIter  
Informs the iterator that it may discard its internal data structures.

**doubleDataArrays** - Variable in class javax.media.jai.RasterAccessor  
The image data in a two-dimensional double array.

**downSampler** - Variable in class javax.media.jai.ImageMIPMap  
The operation chain used to derive the lower resolution images.

**draw(Shape)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**draw(Shape)** - Method in class javax.media.jai.TiledImageGraphics

**draw(Shape)** - Method in class javax.media.jai.RenderableGraphics

**draw3DRect(int, int, int, int, boolean)** - Method in class javax.media.jai.TiledImageGraphics

**draw3DRect(int, int, int, int, boolean)** - Method in class javax.media.jai.RenderableGraphics

**drawArc(int, int, int, int, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**drawArc(int, int, int, int, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**drawArc(int, int, int, int, int, int)** - Method in class javax.media.jai.RenderableGraphics

**drawBorder** - Variable in class javax.media.jai.widget.ImageCanvas

**drawGlyphVector(GlyphVector, float, float)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**drawGlyphVector(GlyphVector, float, float)** - Method in class javax.media.jai.TiledImageGraphics

**drawGlyphVector(GlyphVector, float, float)** - Method in class javax.media.jai.RenderableGraphics

**drawImage(BufferedImage, BufferedImageOp, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**drawImage(BufferedImage, BufferedImageOp, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**drawImage(BufferedImage, BufferedImageOp, int, int)** - Method in class javax.media.jai.RenderableGraphics

**drawImage(Image, AffineTransform, ImageObserver)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**drawImage(Image, AffineTransform, ImageObserver)** - Method in class javax.media.jai.TiledImageGraphics

**drawImage(Image, AffineTransform, ImageObserver)** - Method in class javax.media.jai.RenderableGraphics

**drawImage(Image, int, int, Color, ImageObserver)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**drawImage(Image, int, int, Color, ImageObserver)** - Method in class javax.media.jai.TiledImageGraphics

**drawImage(Image, int, int, Color, ImageObserver)** - Method in class javax.media.jai.RenderableGraphics

**drawImage(Image, int, int, ImageObserver)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**drawImage(Image, int, int, ImageObserver)** - Method in class javax.media.jai.TiledImageGraphics

**drawImage(Image, int, int, ImageObserver)** - Method in class javax.media.jai.RenderableGraphics

**drawImage(Image, int, int, int, int, Color, ImageObserver)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**drawImage(Image, int, int, int, int, Color, ImageObserver)** - Method in class javax.media.jai.TiledImageGraphics

**drawImage(Image, int, int, int, int, Color, ImageObserver)** - Method in class javax.media.jai.RenderableGraphics

**drawImage(Image, int, int, int, int, ImageObserver)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**drawImage(Image, int, int, int, int, ImageObserver)** - Method in class javax.media.jai.TiledImageGraphics

**drawImage(Image, int, int, int, int, ImageObserver)** - Method in class javax.media.jai.RenderableGraphics

**drawImage(Image, int, int, int, int, int, int, int, int, Color, ImageObserver)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**drawImage(Image, int, int, int, int, int, int, int, int, Color, ImageObserver)** - Method in class javax.media.jai.TiledImageGraphics

**drawImage(Image, int, int, int, int, int, int, int, int, Color, ImageObserver)** - Method in class javax.media.jai.RenderableGraphics

**drawImage(Image, int, int, int, int, int, int, int, int, ImageObserver)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**drawImage(Image, int, int, int, int, int, int, int, int, ImageObserver)** - Method in class javax.media.jai.TiledImageGraphics

**drawImage(Image, int, int, int, int, int, int, int, int, ImageObserver)** - Method in class javax.media.jai.RenderableGraphics

**drawLine(int, int, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**drawLine(int, int, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**drawLine(int, int, int, int)** - Method in class javax.media.jai.RenderableGraphics

**drawOval(int, int, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**drawOval(int, int, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**drawOval(int, int, int, int)** - Method in class javax.media.jai.RenderableGraphics

**drawPolygon(int[], int[], int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**drawPolygon(int[], int[], int)** - Method in class javax.media.jai.TiledImageGraphics

**drawPolygon(int[], int[], int)** - Method in class javax.media.jai.RenderableGraphics

**drawPolyline(int[], int[], int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**drawPolyline(int[], int[], int)** - Method in class javax.media.jai.TiledImageGraphics

**drawPolyline(int[], int[], int)** - Method in class javax.media.jai.RenderableGraphics

**drawRenderableImage(RenderableImage, AffineTransform)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**drawRenderableImage(RenderableImage, AffineTransform)** - Method in class javax.media.jai.TiledImageGraphics

**drawRenderableImage(RenderableImage, AffineTransform)** - Method in class javax.media.jai.RenderableGraphics

**drawRenderedImage(RenderedImage, AffineTransform)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**drawRenderedImage(RenderedImage, AffineTransform)** - Method in class javax.media.jai.TiledImageGraphics

**drawRenderedImage(RenderedImage, AffineTransform)** - Method in class javax.media.jai.RenderableGraphics

**drawRoundRect(int, int, int, int, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**drawRoundRect(int, int, int, int, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**drawRoundRect(int, int, int, int, int, int)** - Method in class javax.media.jai.RenderableGraphics

**drawString(AttributedCharacterIterator, float, float)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**drawString(AttributedCharacterIterator, float, float)** - Method in class javax.media.jai.TiledImageGraphics

**drawString(AttributedCharacterIterator, float, float)** - Method in class javax.media.jai.RenderableGraphics

**drawString(AttributedCharacterIterator, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**drawString(AttributedCharacterIterator, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**drawString(AttributedCharacterIterator, int, int)** - Method in class javax.media.jai.RenderableGraphics

**drawString(String, float, float)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**drawString(String, float, float)** - Method in class javax.media.jai.TiledImageGraphics

**drawString(String, float, float)** - Method in class javax.media.jai.RenderableGraphics

**drawString(String, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**drawString(String, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**drawString(String, int, int)** - Method in class javax.media.jai.RenderableGraphics

**duplicate(RenderedOp, RenderedImage)** - Method in class javax.media.jai.ImageMIPMap  
Duplicates a RenderedOp chain.

**duplicate(RenderedOp, RenderedImage, RenderedImage)** - Method in class javax.media.jai.ImageMIPMap  
Duplicates a RenderedOp chain.

**duplicate(RenderedOp, Vector)** - Method in class javax.media.jai.ImageMIPMap  
Duplicates a RenderedOp chain.

**dx** - Variable in class javax.media.jai.ROIShape.PolyShape.PolyEdge  
Change in X with respect to Y.

---

## E

**encode(Raster, ColorModel)** - Method in class com.sun.media.jai.codec.ImageEncoderImpl  
Encodes a Raster with a given ColorModel and writes the output to the OutputStream associated with this ImageEncoder.

**encode(Raster, ColorModel)** - Method in interface com.sun.media.jai.codec.ImageEncoder  
Encodes a Raster with a given ColorModel and writes the output to the OutputStream associated with this ImageEncoder.

**encode(RenderedImage)** - Method in class com.sun.media.jai.codec.ImageEncoderImpl  
Encodes a RenderedImage and writes the output to the OutputStream associated with this ImageEncoder.

**encode(RenderedImage)** - Method in interface com.sun.media.jai.codec.ImageEncoder  
Encodes a RenderedImage and writes the output to the OutputStream associated with this ImageEncoder.

**EncodeDescriptor** - class javax.media.jai.operator.EncodeDescriptor.  
An OperationDescriptor describing the "Encode" operation.

**EncodeDescriptor()** - Constructor for class javax.media.jai.operator.EncodeDescriptor  
Constructor.

**encodeParam** - Variable in class com.sun.media.jai.codec.PNGDecodeParam

**endBands()** - Method in interface javax.media.jai.iterator.RookIter  
Sets the iterator to the last band of the image.

**endDrag()** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Called at the end of a mouse drag.

**endLines()** - Method in interface javax.media.jai.iterator.RookIter  
Sets the iterator to the last line of its bounding rectangle.

**endPixels()** - Method in interface javax.media.jai.iterator.RookIter  
Sets the iterator to the rightmost pixel of its bounding rectangle.

**equals(Object)** - Method in class javax.media.jai.PerspectiveTransform  
Tests if this PerspectiveTransform equals a supplied one.

**ERROR\_FILTER\_FLOYD\_STEINBERG** - Static variable in class javax.media.jai.KernelJAI  
Floyd and Steinberg error filter (1975).

**ERROR\_FILTER\_JARVIS** - Static variable in class javax.media.jai.KernelJAI  
Jarvis, Judice, and Ninke error filter (1976).

**ERROR\_FILTER\_STUCKI** - Static variable in class javax.media.jai.KernelJAI  
Stucki error filter (1981).

**ErrorDiffusionDescriptor** - class javax.media.jai.operator.ErrorDiffusionDescriptor.  
An OperationDescriptor describing the "ErrorDiffusion" operation.

**ErrorDiffusionDescriptor()** - Constructor for class javax.media.jai.operator.ErrorDiffusionDescriptor  
Constructor.

**evaluateOpList(Graphics2D)** - Method in class javax.media.jai.RenderableGraphics  
Evaluate the queue of Graphics2D operations on the specified Graphics2D object.

**exclusiveOr(ROI)** - Method in class javax.media.jai.ROI  
Exclusive-ors the ROI with another ROI and returns the result as a new ROI.

**exclusiveOr(ROI)** - Method in class javax.media.jai.ROIShape  
Sets the mask to its exclusive-or with another mask.

**EXPANDED** - Static variable in class javax.media.jai.RasterAccessor  
Flag indicating ColorModel data should be interpreted.

**expandGrayAlpha** - Variable in class com.sun.media.jai.codec.PNGDecodeParam

**expandPalette** - Variable in class com.sun.media.jai.codec.PNGDecodeParam

**EXPANSION\_MASK** - Static variable in class javax.media.jai.RasterAccessor  
The bits of a FormatTag associated with how ColorModels are used.

**EXPANSION\_MASK\_SHIFT** - Static variable in class javax.media.jai.RasterAccessor  
Value indicating how far EXPANSION\_MASK info is shifted to avoid interfering with the data type info.

**EXPANSION\_MASK\_SIZE** - Static variable in class javax.media.jai.RasterAccessor  
Value indicating how many bits the EXPANSION\_MASK is

**ExpDescriptor** - class javax.media.jai.operator.ExpDescriptor.  
An OperationDescriptor describing the "Exp" operation.

**ExpDescriptor()** - Constructor for class javax.media.jai.operator.ExpDescriptor  
Constructor.

**extend(WritableRaster, PlanarImage)** - Method in class javax.media.jai.BorderExtender  
Fills in the portions of a given Raster that lie outside the bounds of a given PlanarImage with data derived from that PlanarImage.

**extend(WritableRaster, PlanarImage)** - Method in class javax.media.jai.BorderExtenderCopy  
Fills in the portions of a given Raster that lie outside the bounds of a given PlanarImage with copies of the edge pixels of the image.

**extend(WritableRaster, PlanarImage)** - Method in class javax.media.jai.BorderExtenderWrap  
 Fills in the portions of a given Raster that lie outside the bounds of a given PlanarImage with copies of the entire image.

**extend(WritableRaster, PlanarImage)** - Method in class javax.media.jai.BorderExtenderZero  
 Fills in the portions of a given Raster that lie outside the bounds of a given PlanarImage with zeros.

**extend(WritableRaster, PlanarImage)** - Method in class javax.media.jai.BorderExtenderReflect  
 Fills in the portions of a given Raster that lie outside the bounds of a given PlanarImage with suitably reflected copies of the entire image.

**extend(WritableRaster, PlanarImage)** - Method in class javax.media.jai.BorderExtenderConstant  
 Fills in the portions of a given Raster that lie outside the bounds of a given PlanarImage with constant values.

**extender** - Variable in class javax.media.jai.ScaleOpImage  
 The BorderExtender, or null.

**extender** - Variable in class javax.media.jai.AreaOpImage  
 The BorderExtender, may be null.

**extenders** - Variable in class javax.media.jai.OpImage  
 An array of BorderExtenders, one per source, or null.

**ExtremaDescriptor** - class javax.media.jai.operator.ExtremaDescriptor.  
 An OperationDescriptor describing the "Extrema" operation.

**ExtremaDescriptor()** - Constructor for class javax.media.jai.operator.ExtremaDescriptor  
 Constructor.

---

## F

**fAbs(float)** - Static method in class javax.media.jai.KernelJAI  
 Computing the absolute value of a float type

**fieldIndex** - Variable in class com.sun.media.jai.codec.TIFFDirectory  
 A Hashtable indexing the fields by tag number.

**fields** - Variable in class com.sun.media.jai.codec.TIFFDirectory  
 An array of TIFFFields.

**fieldValid** - Variable in class javax.media.jai.RemoteImage  
 Valid bits for locally cached variables.

**file** - Variable in class com.sun.media.jai.codec.FileSeekableStream

**FileCacheSeekableStream** - class com.sun.media.jai.codec.FileCacheSeekableStream.  
 A subclass of SeekableStream that may be used to wrap a regular InputStream.

**FileCacheSeekableStream(InputStream)** - Constructor for class com.sun.media.jai.codec.FileCacheSeekableStream  
 Constructs a MemoryCacheSeekableStream that takes its source data from a regular InputStream.

**FileLoadDescriptor** - class javax.media.jai.operator.FileLoadDescriptor.  
 An OperationDescriptor describing the "FileLoad" operation.

**FileLoadDescriptor()** - Constructor for class javax.media.jai.operator.FileLoadDescriptor  
 Constructor.

**FileSeekableStream** - class com.sun.media.jai.codec.FileSeekableStream.  
 A subclass of SeekableStream that takes its input from a File or RandomAccessFile.

**FileSeekableStream(File)** - Constructor for class com.sun.media.jai.codec.FileSeekableStream  
 Constructs a FileSeekableStream from a File.

**FileSeekableStream(RandomAccessFile)** - Constructor for class com.sun.media.jai.codec.FileSeekableStream  
 Constructs a FileSeekableStream from a RandomAccessFile.

**FileSeekableStream(String)** - Constructor for class com.sun.media.jai.codec.FileSeekableStream  
 Constructs a FileSeekableStream from a String path name.

**FileStoreDescriptor** - class javax.media.jai.operator.FileStoreDescriptor.  
 An OperationDescriptor describing the "FileStore" operation.

**FileStoreDescriptor()** - Constructor for class javax.media.jai.operator.FileStoreDescriptor  
 Constructor.

**fill(Shape)** - Method in class javax.media.jai.GraphicsJAI  
 See comments in java.awt.Graphics2D.

**fill(Shape)** - Method in class javax.media.jai.TiledImageGraphics

**fill(Shape)** - Method in class javax.media.jai.RenderableGraphics

**fill3DRect(int, int, int, int, boolean)** - Method in class javax.media.jai.TiledImageGraphics

**fill3DRect(int, int, int, int, boolean)** - Method in class javax.media.jai.RenderableGraphics

**fillArc(int, int, int, int, int, int)** - Method in class javax.media.jai.GraphicsJAI  
 See comments in java.awt.Graphics.

**fillArc(int, int, int, int, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**fillArc(int, int, int, int, int, int)** - Method in class javax.media.jai.RenderableGraphics

**fillOval(int, int, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**fillOval(int, int, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**fillOval(int, int, int, int)** - Method in class javax.media.jai.RenderableGraphics

**fillPolygon(int[], int[], int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**fillPolygon(int[], int[], int)** - Method in class javax.media.jai.TiledImageGraphics

**fillPolygon(int[], int[], int)** - Method in class javax.media.jai.RenderableGraphics

**fillRect(int, int, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**fillRect(int, int, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**fillRect(int, int, int, int)** - Method in class javax.media.jai.RenderableGraphics

**fillRoundRect(int, int, int, int, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**fillRoundRect(int, int, int, int, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**fillRoundRect(int, int, int, int, int, int)** - Method in class javax.media.jai.RenderableGraphics

**filterRow(byte[], byte[], byte[][], int, int)** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Performs filtering on a row of an image.

**finalize()** - Method in class javax.media.jai.PlanarImage  
Performs cleanup prior to garbage collection.

**finalize()** - Method in class javax.media.jai.OpImage  
Uncache all tiles when this image is garbage collected.

**finalize()** - Method in class javax.media.jai.RemoteImage

**finalize()** - Method in class com.sun.media.jai.codec.SeekableStream  
Releases any system resources associated with this stream by calling the `close()` method.

**findCompatibleTag(SampleModel[], SampleModel)** - Static method in class javax.media.jai.RasterAccessor  
Returns the most efficient FormatTagID that is compatible with the destination SampleModel and all source SampleModel.

**findCompatibleTags(RenderedImage[], RenderedImage)** - Static method in class javax.media.jai.RasterAccessor  
Finds the appropriate tags for the constructor, based on the SampleModel and ColorModel of all the source and destination.

**findCRIF()** - Method in class javax.media.jai.RenderableOp  
Use registry to find an appropriate CRIF

**findNearestEntry(float[])** - Method in class javax.media.jai.LookupTableJAI  
Determine which entry in the `LookupTableJAI` is closest in Euclidean distance to the argument pixel.

**findNearestEntry(float[])** - Method in class javax.media.jai.ColorCube  
Find the index of the nearest color in the color map to the pixel value argument.

**finishedBands()** - Method in interface javax.media.jai.iterator.RectIter  
Returns true if the max band in the image has been exceeded.

**finishedLines()** - Method in interface javax.media.jai.iterator.RectIter  
Returns true if the bottom row of the bounding rectangle has been passed.

**finishedPixels()** - Method in interface javax.media.jai.iterator.RectIter  
Returns true if the right edge of the bounding rectangle has been passed.

**FLIP\_ANTIDIAGONAL** - Static variable in class javax.media.jai.operator.TransposeDescriptor

**FLIP\_DIAGONAL** - Static variable in class javax.media.jai.operator.TransposeDescriptor

**FLIP\_HORIZONTAL** - Static variable in class javax.media.jai.operator.TransposeDescriptor

**FLIP\_VERTICAL** - Static variable in class javax.media.jai.operator.TransposeDescriptor

**flipX(WritableRaster)** - Method in class javax.media.jai.BorderExtenderReflect

**flipY(WritableRaster)** - Method in class javax.media.jai.BorderExtenderReflect

**FLOAT\_ZERO\_TOL** - Static variable in class javax.media.jai.KernelJAI

**floatDataArrays** - Variable in class javax.media.jai.RasterAccessor

The image data in a two-dimensional float array.

**FloatDoubleColorModel** - class javax.media.jai.FloatDoubleColorModel.

A ColorModel class that works with pixel values that represent color and alpha information as separate samples, using float or double elements.

**FloatDoubleColorModel(ColorSpace, boolean, boolean, int, int)** - Constructor for class javax.media.jai.FloatDoubleColorModel

Constructs a ComponentColorModel from the specified parameters.

**flush()** - Method in interface javax.media.jai.TileCache

Advises the cache that all of its tiles may be discarded.

**font** - Variable in class javax.media.jai.TiledImageGraphics

**font** - Variable in class javax.media.jai.RenderableGraphics

**FormatDescriptor** - class javax.media.jai.operator.FormatDescriptor.

An OperationDescriptor describing the "Format" operation.

**FormatDescriptor()** - Constructor for class javax.media.jai.operator.FormatDescriptor  
Constructor.

**formatTagID** - Variable in class javax.media.jai.RasterFormatTag

**formatTagID** - Variable in class javax.media.jai.RasterAccessor

Tag indicating the data type of the data and whether its copied

**formatTags** - Variable in class javax.media.jai.OplImage

The default RasterAccessor format tags.

**formatter** - Static variable in class javax.media.jai.OperationRegistry

Required to I18N compound messages.

**ForwardSeekableStream** - class com.sun.media.jai.codec.ForwardSeekableStream.

A subclass of SeekableStream that may be used to wrap a regular InputStream efficiently.

**ForwardSeekableStream(InputStream)** - Constructor for class com.sun.media.jai.codec.ForwardSeekableStream

Constructs a InputStreamForwardSeekableStream from a regular InputStream.

**foundEOF** - Variable in class com.sun.media.jai.codec.FileCacheSeekableStream

True if we've encountered the end of the source stream.

**foundEOS** - Variable in class com.sun.media.jai.codec.MemoryCacheSeekableStream

True if we've previously reached the end of the source stream

**FPXDecodeParam** - class com.sun.media.jai.codec.FPXDecodeParam.

An instance of ImageDecodeParam for decoding images in the FlashPIX format.

**FPXDecodeParam()** - Constructor for class com.sun.media.jai.codec.FPXDecodeParam

Constructs a default instance of FPXDecodeParam.

**FPXDecodeParam(int)** - Constructor for class com.sun.media.jai.codec.FPXDecodeParam

Constructs an instance of FPXDecodeParam to decode a given resolution.

**FPXDescriptor** - class javax.media.jai.operator.FPXDescriptor.

An OperationDescriptor describing the "FPX" operation.

**FPXDescriptor()** - Constructor for class javax.media.jai.operator.FPXDescriptor  
Constructor.

**frequency** - Variable in class com.sun.media.jai.codec.PNGSuggestedPaletteEntry

The probable frequency of the color in the image.

---

## G

**g** - Variable in class javax.media.jai.GraphicsJAI

**gamma** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**gammaSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**generateEncodeParam** - Variable in class com.sun.media.jai.codec.PNGDecodeParam

**getAdjustedOffset()** - Method in class javax.media.jai.ColorCube

Get the adjusted offset into the lookup table, accounting for negative dimensions.

**getAlpha(int)** - Method in class javax.media.jai.FloatDoubleColorModel

Throws an IllegalArgumentException, since pixel values for this ColorModel are not conveniently representable as a single int.

**getAlpha(Object)** - Method in class javax.media.jai.FloatDoubleColorModel

Returns the alpha component for the specified pixel, scaled from 0 to 255.

**getAppropriateDataType(SampleModel)** - Static method in class javax.media.jai.OpImage

**getAsBitmask(int, int, int, int, int[][])** - Method in class javax.media.jai.ROI

Returns a bitmask for a given rectangular region of the ROI indicating whether the pixel is included in the region of interest.

**getAsBitmask(int, int, int, int, int[][])** - Method in class javax.media.jai.ROIShape

Returns a bitmask for a given rectangular region of the ROI indicating whether the pixel is included in the region of interest.

**getAsBufferedImage()** - Method in class javax.media.jai.PlanarImage

Returns a copy of the entire image as a BufferedImage.

**getAsBufferedImage(Rectangle, ColorModel)** - Method in class javax.media.jai.PlanarImage

Returns a copy of this image as a BufferedImage.

**getAsBytes()** - Method in class com.sun.media.jai.codec.TIFFField

Returns the data as an uninterpreted array of bytes.

**getAsChars()** - Method in class com.sun.media.jai.codec.TIFFField

Returns TIFF\_SHORT data as an array of chars (unsigned 16-bit integers).

**getAsDouble(int)** - Method in class com.sun.media.jai.codec.TIFFField

Returns data in any numerical format as a float.

**getAsDoubles()** - Method in class com.sun.media.jai.codec.TIFFField

Returns TIFF\_DOUBLE data as an array of doubles.

**getAsFloat(int)** - Method in class com.sun.media.jai.codec.TIFFField

Returns data in any numerical format as a float.

**getAsFloats()** - Method in class com.sun.media.jai.codec.TIFFField

Returns TIFF\_FLOAT data as an array of floats.

**getAsImage()** - Method in class javax.media.jai.ROI

Returns a PlanarImage representation of the ROI.

**getAsImage()** - Method in class javax.media.jai.ROIShape

Returns the shape as a PlanarImage.

**getAsInt(int)** - Method in class com.sun.media.jai.codec.TIFFField

Returns data in TIFF\_BYTE, TIFF\_SBYTE, TIFF\_UNDEFINED, TIFF\_SHORT, TIFF\_SSHORT, or TIFF\_SLONG format as an int.

**getAsInts()** - Method in class com.sun.media.jai.codec.TIFFField

Returns TIFF\_SLONG data as an array of ints (signed 32-bit integers).

**getAsLong(int)** - Method in class com.sun.media.jai.codec.TIFFField

Returns data in TIFF\_BYTE, TIFF\_SBYTE, TIFF\_UNDEFINED, TIFF\_SHORT, TIFF\_SSHORT, TIFF\_SLONG, or TIFF\_LONG format as a long.

**getAsLongs()** - Method in class com.sun.media.jai.codec.TIFFField

Returns TIFF\_LONG data as an array of longs (signed 64-bit integers).

**getAsRational(int)** - Method in class com.sun.media.jai.codec.TIFFField

Returns a TIFF\_RATIONAL data item as a two-element array of ints.

**getAsRationals()** - Method in class com.sun.media.jai.codec.TIFFField

Returns TIFF\_RATIONAL data as an array of 2-element arrays of longs.

**getAsRectangleList(int, int, int, int)** - Method in class javax.media.jai.ROI

Returns a LinkedList of Rectangles for a given rectangular region of the ROI.

**getAsRectangleList(int, int, int, int)** - Method in class javax.media.jai.ROIShape

Returns a LinkedList of Rectangles for a given rectangular region of the ROI.

**getAsRectangleList(int, int, int, int, boolean)** - Method in class javax.media.jai.ROI

Returns a LinkedList of Rectangles for a given rectangular region of the ROI.

**getAsRectangleList(int, int, int, int, boolean)** - Method in class javax.media.jai.ROIShape

Returns a LinkedList of Rectangles for a given rectangular region of the ROI.

**getAsRectList()** - Method in class javax.media.jai.ROIShape.PolyShape

Perform scan conversion of the PolyShape to generate a LinkedList of Rectangles.

**getAsRenderable()** - Method in class javax.media.jai.ImageMIPMap

Returns the current image as a RenderableImage.

**getAsRenderable(int, float, float, float)** - Method in class javax.media.jai.ImageMIPMap

Returns the current image as a RenderableImage.

**getAsShape()** - Method in class javax.media.jai.ROI

Returns a Shape representation of the ROI, if possible.

**getAsShape()** - Method in class javax.media.jai.ROIShape

Returns the internal Shape representation or null if a shape representation is not possible.

**getAsShorts()** - Method in class com.sun.media.jai.codec.TIFFField

Returns TIFF\_SSHORT data as an array of shorts (signed 16-bit integers).

**getAsSRational(int)** - Method in class com.sun.media.jai.codec.TIFFField

Returns a TIFF\_SRATIONAL data item as a two-element array of ints.

**getAsSRationals()** - Method in class com.sun.media.jai.codec.TIFFField

Returns TIFF\_SRATIONAL data as an array of 2-element arrays of ints.

**getAsString(int)** - Method in class com.sun.media.jai.codec.TIFFField

Returns a TIFF\_ASCII data item as a String.

**getBackground()** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**getBackground()** - Method in class javax.media.jai.TiledImageGraphics

**getBackground()** - Method in class javax.media.jai.RenderableGraphics

**getBackgroundGray()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Gray  
Returns the suggested gray level of the background.

**getBackgroundPaletteIndex()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Palette  
Returns the palette index of the suggested background color.

**getBackgroundRGB()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.RGB  
Returns the RGB value of the suggested background color.

**getBandOffset(int)** - Method in class javax.media.jai.RasterAccessor  
Returns the offset of a specific band's first sample into the DataBuffer including the DataBuffer's offset.

**getBandOffsets()** - Method in class javax.media.jai.RasterFormatTag  
Returns the bandOffsets for the Raster if isPixelSequential() is true.

**getBandOffsets()** - Method in class javax.media.jai.RasterAccessor  
Returns the bandDataOffsets into the dataArrays.

**getBankData()** - Method in class javax.media.jai.DataBufferDouble  
Returns the data array for all banks.

**getBankData()** - Method in class javax.media.jai.DataBufferFloat  
Returns the data array for all banks.

**getBankIndices()** - Method in class javax.media.jai.RasterFormatTag  
Returns the bankIndices for the Raster if isPixelSequential() is true.

**getBinLowValue(int, int)** - Method in class javax.media.jai.Histogram  
Returns the lowest pixel value found in a given bin for a given band.

**getBins()** - Method in class javax.media.jai.Histogram  
Returns the bins of the histogram for all bands.

**getBins(int)** - Method in class javax.media.jai.Histogram  
Returns the bins of the histogram for a specified band.

**getBinSize(int, int)** - Method in class javax.media.jai.Histogram  
Returns the number of pixel values found in a given bin for a given band.

**getBitDepth()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns the desired bit depth for a grayscale image.

**getBitShift()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Gray  
Returns the desired bit shift for a grayscale image.

**getBlue(int)** - Method in class javax.media.jai.FloatDoubleColorModel  
Throws an `IllegalArgumentException`, since pixel values for this `ColorModel` are not conveniently representable as a single `int`.

**getBlue(Object)** - Method in class javax.media.jai.FloatDoubleColorModel  
Returns the blue color component for the specified pixel, scaled from 0 to 255 in the default RGB ColorSpace, sRGB.

**getBogusGraphics2D()** - Method in class javax.media.jai.RenderableGraphics  
Creates a bogus `Graphics2D` object to be used to retrieve information dependent on system aspects which are image-independent.

**getBogusGraphics2D(boolean)** - Method in class javax.media.jai.TiledImageGraphics  
Creates a bogus `Graphics2D` object to be used to retrieve information dependent on system aspects which are image-independent.

**getBottomPadding()** - Method in class javax.media.jai.Interpolation  
Returns the number of samples required below the center.

**getBottomPadding()** - Method in class javax.media.jai.WarpOpImage  
Returns the number of samples required below the center.

**getBottomPadding()** - Method in class javax.media.jai.AreaOpImage  
Returns the number of pixels needed below the central pixel.

**getBottomPadding()** - Method in class javax.media.jai.KernelJAI  
Returns the number of pixels required below the key element.

**getBoundingBox(int[], int[], int)** - Static method in class javax.media.jai.TiledImageGraphics  
Determine the bounding box of the points represented by the supplied arrays of X and Y coordinates.

**getBounds()** - Method in class javax.media.jai.PlanarImage  
Returns a `Rectangle` indicating the image bounds.

**getBounds()** - Method in class javax.media.jai.ROI  
Returns the bounds of the ROI as a `Rectangle`.

**getBounds()** - Method in class javax.media.jai.ROIShape  
Returns the bounds of the mask as a `Rectangle`.

**getBounds2D()** - Method in class javax.media.jai.ROI  
Returns the bounds of the ROI as a `Rectangle2D`.

**getBounds2D()** - Method in class javax.media.jai.ROIShape  
Returns the bounds of the mask as a `Rectangle2D`.

**getBufferSize()** - Method in class javax.media.jai.ComponentSampleModelJAI  
Returns the size of the data buffer (in data elements) needed for a data buffer that matches this ComponentSampleModel.

**getByteData()** - Method in class javax.media.jai.LookupTableJAI  
Returns the byte table data in array format, or null if the table's data type is not byte.

**getByteData(int)** - Method in class javax.media.jai.LookupTableJAI  
Returns the byte table data of a specific band in array format, or null if the table's data type is not byte.

**getByteDataArray(int)** - Method in class javax.media.jai.RasterAccessor  
Returns the image data as a byte array for a specific band.

**getByteDataArrays()** - Method in class javax.media.jai.RasterAccessor  
Returns the image data as a byte array.

**getByteParameter(int)** - Method in class javax.media.jai.RenderedOp  
Returns the specified parameter stored in the ParameterBlock of this node as a byte.

**getByteParameter(int)** - Method in class javax.media.jai.RenderableOp  
Returns one of the node's parameters, as a byte.

**getByteParameter(String)** - Method in class javax.media.jai.ParameterBlockJAI  
A convenience method to return a parameter as a byte.

**getCameraPosition(PlanarImage)** - Method in class javax.media.jai.ImageSequence  
Returns the camera position associated with the specified image, or null if pi is null or if no match is found.

**getCharParameter(int)** - Method in class javax.media.jai.RenderedOp  
Returns the specified parameter stored in the ParameterBlock of this node as a char.

**getCharParameter(int)** - Method in class javax.media.jai.RenderableOp  
Returns one of the node's parameters, as a char.

**getCharParameter(String)** - Method in class javax.media.jai.ParameterBlockJAI  
A convenience method to return a parameter as a char.

**getChromaticity()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns the white point and primary chromaticities in CIE (x, y) space.

**getClip()** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**getClip()** - Method in class javax.media.jai.TiledImageGraphics

**getClip()** - Method in class javax.media.jai.RenderableGraphics

**getClipBounds()** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**getClipBounds()** - Method in class javax.media.jai.TiledImageGraphics

**getClipBounds()** - Method in class javax.media.jai.RenderableGraphics

**getCodec(String)** - Static method in class com.sun.media.jai.codec.ImageCodec  
Returns the ImageCodec associated with the given name.

**getCodecs()** - Static method in class com.sun.media.jai.codec.ImageCodec  
Returns an Enumeration of all registered ImageCodec objects.

**getCoeffs()** - Method in class javax.media.jai.WarpPolynomial  
Returns the raw coefficients array for both the X and Y coordinates.

**getCollection()** - Method in class javax.media.jai.CollectionOp  
Returns the collection rendering associated with this operation.

**getColor()** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**getColor()** - Method in class javax.media.jai.TiledImageGraphics

**getColor()** - Method in class javax.media.jai.RenderableGraphics

**getColorModel()** - Method in class javax.media.jai.PlanarImage  
Returns the ColorModel of the image.

**getColorModel()** - Method in class javax.media.jai.RenderedOp  
Returns the node if it has not already been rendered, and returns the ColorModel of the rendered image.

**getColorModel()** - Method in class javax.media.jai.RemoteImage  
Returns the ColorModel associated with this image.

**getColorModel(RenderedImage)** - Method in class javax.media.jai.ImageLayout  
Returns the value of colorModel if it is valid, and otherwise returns the value from the supplied RenderedImage.

**getColorModel(TiledImage)** - Static method in class javax.media.jai.TiledImageGraphics  
Derive an appropriate ColorModel for use with the underlying BufferedImage canvas.

**getComponents(int, int[], int)** - Method in class javax.media.jai.FloatDoubleColorModel  
Throws an IllegalArgumentException, since pixel values for this ColorModel are not conveniently representable as a single int.

**getComponents(Object, int[], int)** - Method in class javax.media.jai.FloatDoubleColorModel  
Throws an IllegalArgumentException since the pixel values cannot be placed into an int array.

**getComposite()** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**getComposite()** - Method in class javax.media.jai.TiledImageGraphics

**getComposite()** - Method in class javax.media.jai.RenderableGraphics

**getCompressedText()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns the text strings to be stored in compressed form with this image as an array of `Strings`.

**getCompression()** - Method in class com.sun.media.jai.codec.TIFFEncodeParam  
Returns the value of the compression parameter.

**getCoordinate(PlanarImage)** - Method in class javax.media.jai.ImageStack  
Returns the coordinate associated with the specified image, or null if `pi` is null or if no match is found.

**getCopyInDegree()** - Method in class javax.media.jai.PartialOrderNode  
Returns the copy in-degree of this node.

**getCount()** - Method in class com.sun.media.jai.codec.TIFFField  
Returns the number of elements in the IFD.

**getCurrentImage()** - Method in class javax.media.jai.ImageMIPMap  
Returns the image at the current resolution level.

**getCurrentLevel()** - Method in class javax.media.jai.ImageMIPMap  
Returns the current resolution level.

**getData()** - Method in class javax.media.jai.DataBufferDouble  
Returns the default (first) double data array.

**getData()** - Method in class javax.media.jai.PlanarImage  
Returns the entire image in a single `Raster`.

**getData()** - Method in class javax.media.jai.RenderedOp  
Renders the node if it has not already been rendered, and returns the entire rendered image as a `Raster`.

**getData()** - Method in class javax.media.jai.RemoteImage  
Returns the image as one large tile.

**getData()** - Method in class javax.media.jai.RenderedImageAdapter  
Forwards call to the true source.

**getData()** - Method in class javax.media.jai.PartialOrderNode  
Returns the Object represented by this node.

**getData()** - Method in class javax.media.jai.LookupTableJAI  
Returns the table data as a `DataBuffer`.

**getData()** - Method in class javax.media.jai.DataBufferFloat  
Returns the default (first) float data array.

**getData(int)** - Method in class javax.media.jai.DataBufferDouble  
Returns the data array for the specified bank.

**getData(int)** - Method in class javax.media.jai.DataBufferFloat  
Returns the data array for the specified bank.

**getData(Rectangle)** - Method in class javax.media.jai.PlanarImage  
Returns a specified region of this image in a `Raster`.

**getData(Rectangle)** - Method in class javax.media.jai.RenderedOp  
Renders the node if it has not already been rendered, and returns a specified rectangular region of the rendered image as a `Raster`.

**getData(Rectangle)** - Method in class javax.media.jai.RemoteImage  
Returns an arbitrary rectangular region of the `RemoteImage`.

**getData(Rectangle)** - Method in class javax.media.jai.RenderedImageAdapter  
Forwards call to the true source.

**getDataArray(int)** - Method in class javax.media.jai.RasterAccessor  
Returns the image data as an Object for a specific band.

**getDataElement(int[], int)** - Method in class javax.media.jai.FloatDoubleColorModel  
Throws an `IllegalArgumentException`, since pixel values for this `ColorModel` are not conveniently representable as a single `int`.

**getDataElements(int[], int, Object)** - Method in class javax.media.jai.FloatDoubleColorModel  
Returns a data element array representation of a pixel in this `ColorModel`, given an array of unnormalized color/alpha components.

**getDataElements(int, int, int, int, Object, DataBuffer)** - Method in class javax.media.jai.ComponentSampleModelJAI  
Returns the pixel data for the specified rectangle of pixels in a primitive array of type `TransferType`.

**getDataElements(int, int, Object, DataBuffer)** - Method in class javax.media.jai.ComponentSampleModelJAI  
Returns data for a single pixel in a primitive array of type `TransferType`.

**getDataElements(int, Object)** - Method in class javax.media.jai.FloatDoubleColorModel  
Returns a data element array representation of a pixel in this `ColorModel`, given an integer pixel representation in the default RGB color model.

**getDataType()** - Method in class javax.media.jai.LookupTableJAI  
Returns the data type of the table data.

**getDataType()** - Method in class `javax.media.jai.RasterAccessor`  
Returns the data type of the `RasterAccessor` object.

**getDecodePaletteAsShorts()** - Method in class `com.sun.media.jai.codec.TIFFDecodeParam`  
Returns `true` if palette entries will be decoded as shorts, resulting in an output image with short datatype.

**getDecodeParamClass()** - Method in class `com.sun.media.jai.codec.ImageCodec`  
Returns a `Class` object indicating the proper subclass of `ImageDecodeParam` to be used with this `ImageCodec`.

**getDecoderNames(SeekableStream)** - Static method in class `com.sun.media.jai.codec.ImageCodec`  
Returns an array of `Strings` indicating the names of registered `ImageCodecs` that may be appropriate for reading the given `SeekableStream`.

**getDefaultEncodeParam(RenderedImage)** - Static method in class `com.sun.media.jai.codec.PNGEncodeParam`  
Returns an instance of `PNGEncodeParam.Palette`, `PNGEncodeParam.Gray`, or `PNGEncodeParam.RGB` appropriate for encoding the given image.

**getDefaultInstance()** - Static method in class `javax.media.jai.JAI`  
Returns the default JAI instance.

**getDegree()** - Method in class `javax.media.jai.WarpPolynomial`  
Returns the degree of the warp polynomials.

**getDestClass()** - Method in interface `javax.media.jai.OperationDescriptor`  
Returns a `Class` that describes the type of destination this operation produces in the rendered image mode.

**getDestClass()** - Method in class `javax.media.jai.OperationDescriptorImpl`  
Returns the destination class type of this operation for the rendered mode.

**getDestClass()** - Method in class `javax.media.jai.operator.AddConstToCollectionDescriptor`  
Returns the destination's class type of this operation.

**getDestNumBands(int)** - Method in class `javax.media.jai.LookupTableJAI`  
Returns the number of bands of the destination image, based on the number of bands of the source image and lookup table.

**getDestSampleModel(SampleModel)** - Method in class `javax.media.jai.LookupTableJAI`  
Returns a `SampleModel` suitable for holding the output of a lookup operation on the source data described by a given `SampleModel` with this table.

**getDestSampleModel(SampleModel, int, int)** - Method in class `javax.media.jai.LookupTableJAI`  
Returns a `SampleModel` suitable for holding the output of a lookup operation on the source data described by a given `SampleModel` with this table.

**getDeterminant()** - Method in class `javax.media.jai.PerspectiveTransform`  
Returns the determinant of the matrix representation of the transform.

**getDeviceConfiguration()** - Method in class `javax.media.jai.GraphicsJAI`  
See comments in `java.awt.Graphics2D`.

**getDeviceConfiguration()** - Method in class `javax.media.jai.TiledImageGraphics`

**getDeviceConfiguration()** - Method in class `javax.media.jai.RenderableGraphics`

**getDiffImage()** - Method in class `javax.media.jai.ImagePyramid`  
Returns the difference image between the current image and the image obtained by first down sampling the current image then up sampling the result image of down sampling.

**getDimension()** - Method in class `javax.media.jai.ColorCube`  
Returns the array of signed dimensions used to construct the `ColorCube`.

**getDimsLessOne()** - Method in class `javax.media.jai.ColorCube`  
Returns an array containing the signed dimensions, less one.

**getDisplayExponent()** - Method in class `com.sun.media.jai.codec.PNGDecodeParam`  
Returns the current value of the display exponent parameter.

**getDoubleData()** - Method in class `javax.media.jai.LookupTableJAI`  
Returns the double table data in array format, or null if the table's data type is not double.

**getDoubleData(int)** - Method in class `javax.media.jai.LookupTableJAI`  
Returns the double table data of a specific band in array format, or null if table's data type is not double.

**getDoubleDataArray(int)** - Method in class `javax.media.jai.RasterAccessor`  
Returns the image data as a double array for a specific band.

**getDoubleDataArrays()** - Method in class `javax.media.jai.RasterAccessor`  
Returns the image data as a double array.

**getDoubleParameter(int)** - Method in class `javax.media.jai.RenderedOp`  
Returns the specified parameter stored in the `ParameterBlock` of this node as a double.

**getDoubleParameter(int)** - Method in class `javax.media.jai.RenderableOp`  
Returns one of the node's parameters, as a double.

**getDoubleParameter(String)** - Method in class `javax.media.jai.ParameterBlockJAI`  
A convenience method to return a parameter as a double.

**getDownImage()** - Method in class `javax.media.jai.ImageMIPMap`  
Returns the image at the next lower resolution level, obtained by applying the `downSampler` on the image at the current resolution level.

**getDownImage()** - Method in class `javax.media.jai.ImagePyramid`  
Returns the image at the next lower resolution level, obtained by applying the `downSampler` on the image at the current resolution level.

**getElem(int)** - Method in class javax.media.jai.DataBufferDouble  
Returns the requested data array element from the first (default) bank as an `int`.

**getElem(int)** - Method in class javax.media.jai.DataBufferFloat  
Returns the requested data array element from the first (default) bank as an `int`.

**getElem(int, int)** - Method in class javax.media.jai.DataBufferDouble  
Returns the requested data array element from the specified bank as an `int`.

**getElem(int, int)** - Method in class javax.media.jai.DataBufferFloat  
Returns the requested data array element from the specified bank as an `int`.

**getElemDouble(int)** - Method in class javax.media.jai.DataBufferDouble  
Returns the requested data array element from the first (default) bank as a `double`.

**getElemDouble(int)** - Method in class javax.media.jai.DataBufferFloat  
Returns the requested data array element from the first (default) bank as a `double`.

**getElemDouble(int, int)** - Method in class javax.media.jai.DataBufferDouble  
Returns the requested data array element from the specified bank as a `double`.

**getElemDouble(int, int)** - Method in class javax.media.jai.DataBufferFloat  
Returns the requested data array element from the specified bank as a `double`.

**getElement(int, int)** - Method in class javax.media.jai.KernelJAI  
Returns a given element of the kernel.

**getElements(double, double, double, double, int, int, int, double[], double[])** - Method in interface javax.media.jai.ImageFunction  
Returns all values of a given element for a specified set of coordinates.

**getElements(float, float, float, float, int, int, int, float[], float[])** - Method in interface javax.media.jai.ImageFunction  
Returns all values of a given element for a specified set of coordinates.

**getElemFloat(int)** - Method in class javax.media.jai.DataBufferDouble  
Returns the requested data array element from the first (default) bank as a `float`.

**getElemFloat(int)** - Method in class javax.media.jai.DataBufferFloat  
Returns the requested data array element from the first (default) bank as a `float`.

**getElemFloat(int, int)** - Method in class javax.media.jai.DataBufferDouble  
Returns the requested data array element from the specified bank as a `float`.

**getElemFloat(int, int)** - Method in class javax.media.jai.DataBufferFloat  
Returns the requested data array element from the specified bank as a `float`.

**getEncodeParam()** - Method in class com.sun.media.jai.codec.PNGDecodeParam  
If `getGenerateEncodeParam()` is true, this method may be called after decoding has completed, and will return an instance of `PNCEncodeParam` containing information about the contents of the PNG file just decoded.

**getEncodeParamClass()** - Method in class com.sun.media.jai.codec.ImageCodec  
Returns a `Class` object indicating the proper subclass of `ImageEncodeParam` to be used with this `ImageCodec`.

**getEncoderNames(RenderedImage, ImageEncodeParam)** - Static method in class com.sun.media.jai.codec.ImageCodec  
Returns an array of `Strings` indicating the names of registered `ImageCodecs` that may be appropriate for writing the given `RenderedImage`, using the optional `ImageEncodeParam`, which may be null.

**getExpandedNumBands(SampleModel, ColorModel)** - Static method in class javax.media.jai.OpImage  
Returns the effective number of bands of an image with a given `SampleModel` and `ColorModel`.

**getExpandGrayAlpha()** - Method in class com.sun.media.jai.codec.PNGDecodeParam  
Returns the current setting of the gray/alpha expansion.

**getExpandPalette()** - Method in class com.sun.media.jai.codec.PNGDecodeParam  
Returns true if palette-color images will be expanded to produce full-color output.

**getExtendedData(Rectangle, BorderExtender)** - Method in class javax.media.jai.PlanarImage  
Returns a copy of an arbitrary rectangular region of this image in a `Raster`.

**getField(int)** - Method in class com.sun.media.jai.codec.TIFFDirectory  
Returns the value of a given tag as a `TIFFField`, or null if the tag is not present.

**getFieldAsByte(int)** - Method in class com.sun.media.jai.codec.TIFFDirectory  
Returns the value of index 0 of a given tag as a `byte`.

**getFieldAsByte(int, int)** - Method in class com.sun.media.jai.codec.TIFFDirectory  
Returns the value of a particular index of a given tag as a `byte`.

**getFieldAsDouble(int)** - Method in class com.sun.media.jai.codec.TIFFDirectory  
Returns the value of index 0 of a given tag as a `double`.

**getFieldAsDouble(int, int)** - Method in class com.sun.media.jai.codec.TIFFDirectory  
Returns the value of a particular index of a given tag as a `double`.

**getFieldAsFloat(int)** - Method in class com.sun.media.jai.codec.TIFFDirectory  
Returns the value of index 0 of a given tag as a `float`.

**getFieldAsFloat(int, int)** - Method in class com.sun.media.jai.codec.TIFFDirectory  
Returns the value of a particular index of a given tag as a `float`.

**getFieldAsLong(int)** - Method in class com.sun.media.jai.codec.TIFFDirectory  
Returns the value of index 0 of a given tag as a `long`.

**getFieldAsLong(int, int)** - Method in class com.sun.media.jai.codec.TIFFDirectory  
Returns the value of a particular index of a given tag as a `long`.

**getFields()** - Method in class com.sun.media.jai.codec.TIFFDirectory  
Returns an array of `TIFFFields` containing all the fields in this directory.

**getFilePointer()** - Method in class `com.sun.media.jai.codec.SeekableStream`  
Returns the current offset in this stream.

**getFilePointer()** - Method in class `com.sun.media.jai.codec.ForwardSeekableStream`  
Returns the current position in the stream (bytes read).

**getFilePointer()** - Method in class `com.sun.media.jai.codec.SegmentedSeekableStream`  
Returns the current offset in this stream.

**getFilePointer()** - Method in class `com.sun.media.jai.codec.ByteArraySeekableStream`  
Returns the current offset in this stream.

**getFilePointer()** - Method in class `com.sun.media.jai.codec.MemoryCacheSeekableStream`  
Returns the current offset in this file.

**getFilePointer()** - Method in class `com.sun.media.jai.codec.FileCacheSeekableStream`  
Returns the current offset in this file.

**getFilePointer()** - Method in class `com.sun.media.jai.codec.FileSeekableStream`  
Returns the current offset in this stream.

**getFloatData()** - Method in class `javax.media.jai.LookupTableJAI`  
Returns the float table data in array format, or null if the table's data type is not float.

**getFloatData(int)** - Method in class `javax.media.jai.LookupTableJAI`  
Returns the float table data of a specific band in array format, or null if table's data type is not float.

**getFloatDataArray(int)** - Method in class `javax.media.jai.RasterAccessor`  
Returns the image data as a float array for a specific band.

**getFloatDataArrays()** - Method in class `javax.media.jai.RasterAccessor`  
Returns the image data as a float array.

**getFloatParameter(int)** - Method in class `javax.media.jai.RenderedOp`  
Returns the specified parameter stored in the `ParameterBlock` of this node as a float.

**getFloatParameter(int)** - Method in class `javax.media.jai.RenderableOp`  
Returns one of the node's parameters, as a float.

**getFloatParameter(String)** - Method in class `javax.media.jai.ParameterBlockJAI`  
A convenience method to return a parameter as a float.

**getFont()** - Method in class `javax.media.jai.GraphicsJAI`  
See comments in `java.awt.Graphics`.

**getFont()** - Method in class `javax.media.jai.TiledImageGraphics`

**getFont()** - Method in class `javax.media.jai.RenderableGraphics`

**getFontMetrics(Font)** - Method in class `javax.media.jai.GraphicsJAI`  
See comments in `java.awt.Graphics`.

**getFontMetrics(Font)** - Method in class `javax.media.jai.TiledImageGraphics`

**getFontMetrics(Font)** - Method in class `javax.media.jai.RenderableGraphics`

**getFontRenderContext()** - Method in class `javax.media.jai.GraphicsJAI`  
See comments in `java.awt.Graphics2D`.

**getFontRenderContext()** - Method in class `javax.media.jai.TiledImageGraphics`

**getFontRenderContext()** - Method in class `javax.media.jai.RenderableGraphics`

**getFormatName()** - Method in class `com.sun.media.jai.codec.ImageCodec`  
Returns the name of this image format.

**getFormatTagID()** - Method in class `javax.media.jai.RasterFormatTag`  
Returns the `FormatTagID` used to construct this `RasterFormatTag`.

**getFormatTags()** - Method in class `javax.media.jai.OpImage`  
Returns the image's format tags to be used with a `RasterAccessor`.

**getGamma()** - Method in class `com.sun.media.jai.codec.PNGEncodeParam`  
Returns the file gamma value for the image.

**getGeneratedPropertyNames(String)** - Method in class `javax.media.jai.OperationRegistry`  
Returns a list of the properties generated by nodes implementing the operation associated with a particular Operation Name.

**getGenerateEncodeParam()** - Method in class `com.sun.media.jai.codec.PNGDecodeParam`  
Returns true if an instance of `PNGEncodeParam` will be available after an image has been decoded via the `getEncodeParam` method.

**getGraphics()** - Method in class `javax.media.jai.PlanarImage`  
Returns a `Graphics` object that may be used to draw into this image.

**getGraphics()** - Method in class `javax.media.jai.CanvasJAI`  
Returns an instance of `GraphicsJAI` for drawing to this canvas.

**getGraphics()** - Method in class `javax.media.jai.TiledImage`  
Creates a `Graphics` object that can be used to paint text and graphics onto the `TiledImage`.

**getGreen(int)** - Method in class `javax.media.jai.FloatDoubleColorModel`  
Throws an `IllegalArgumentException`, since pixel values for this `ColorModel` are not conveniently representable as a single int.

**getGreen(Object)** - Method in class javax.media.jai.FloatDoubleColorModel  
Returns the green color component for the specified pixel, scaled from 0 to 255 in the default RGB ColorSpace, sRGB.

**getHeight()** - Method in class javax.media.jai.PlanarImage  
Returns the height of the image.

**getHeight()** - Method in class javax.media.jai.RenderedOp  
Renders the node if it has not already been rendered, and returns the height of the rendered image.

**getHeight()** - Method in class javax.media.jai.Interpolation  
Returns the number of samples required for vertical resampling.

**getHeight()** - Method in class javax.media.jai.RenderableOp  
Return the rendering-independent height of the image.

**getHeight()** - Method in class javax.media.jai.RenderableImageAdapter  
Gets the height in user coordinate space.

**getHeight()** - Method in class javax.media.jai.MultiResolutionRenderableImage  
Returns the floating-point height of the RenderableImage.

**getHeight()** - Method in class javax.media.jai.RemoteImage  
Returns the height of the RemoteImage in pixels.

**getHeight()** - Method in class javax.media.jai.RasterAccessor  
Returns the height of the RasterAccessor's accessible area.

**getHeight()** - Method in class javax.media.jai.RenderableGraphics

**getHeight()** - Method in class javax.media.jai.KernelJAI  
Returns the height of the kernel.

**getHeight(RenderedImage)** - Method in class javax.media.jai.ImageLayout  
Returns the value of height if it is valid, and otherwise returns the value from the supplied RenderedImage.

**getHighValue()** - Method in class javax.media.jai.Histogram  
Returns the highest value checked for all bands.

**getHighValue(int)** - Method in class javax.media.jai.Histogram  
Returns the highest value checked for a specified band.

**getHorizontalKernelData()** - Method in class javax.media.jai.KernelJAI  
Returns the horizontal portion of the kernel if the kernel is separable, or null otherwise.

**getHorizontalSubsampling(int)** - Method in class com.sun.media.jai.codec.JPEGEncodeParam  
Get the horizontal subsampling factor for a band.

**getHorizontalTableData()** - Method in class javax.media.jai.InterpolationTable  
Returns the integer (fixed-point) horizontal table data.

**getHorizontalTableDataDouble()** - Method in class javax.media.jai.InterpolationTable  
Returns the double horizontal table data.

**getHorizontalTableDataFloat()** - Method in class javax.media.jai.InterpolationTable  
Returns the floating-point horizontal table data.

**getICCProfileData()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns the ICC profile data to be stored with this image.

**getImage(float)** - Method in class javax.media.jai.ImageSequence  
Returns the image associated with the specified time stamp, or null if no match is found.

**getImage(int)** - Method in class javax.media.jai.ImageMIPMap  
Returns the image at the specified resolution level.

**getImage(int)** - Method in class javax.media.jai.ImagePyramid  
Returns the image at the specified resolution level.

**getImage(Object)** - Method in class javax.media.jai.ImageSequence  
Returns the image associated with the specified camera position, or null if cp is null or if no match is found.

**getImage(Object)** - Method in class javax.media.jai.ImageStack  
Returns the image associated with the specified coordinate, or null if c is null or if no match is found.

**getInDegree()** - Method in class javax.media.jai.PartialOrderNode  
Returns the in-degree of this node.

**getInputStream()** - Method in class com.sun.media.jai.codec.ImageDecoderImpl  
Returns the SeekableStream associated with this ImageDecoder.

**getInputStream()** - Method in interface com.sun.media.jai.codec.ImageDecoder  
Returns the SeekableStream associated with this ImageDecoder.

**getInstance(int)** - Static method in class javax.media.jai.Interpolation  
Creates an interpolation of one of the standard types.

**getIntData()** - Method in class javax.media.jai.LookupTableJAI  
Returns the integer table data in array format, or null if the table's data type is not int.

**getIntData(int)** - Method in class javax.media.jai.LookupTableJAI  
Returns the integer table data of a specific band in array format, or null if table's data type is not int.

**getIntDataArray(int)** - Method in class javax.media.jai.RasterAccessor  
Returns the image data as an int array for a specific band.

**getIntDataArrays()** - Method in class javax.media.jai.RasterAccessor  
Returns the image data as an int array.

**getInterlacing()** - Method in class `com.sun.media.jai.codec.PNGEncodeParam`  
Returns `true` if Adam7 interlacing will be used.

**getIntersection(double, double, double, double, double, double, double, double)** - Static method in class `javax.media.jai.ROIShape`  
Calculate the point of intersection of two line segments.

**getIntParameter(int)** - Method in class `javax.media.jai.RenderedOp`  
Returns the specified parameter stored in the `ParameterBlock` of this node as an `int`.

**getIntParameter(int)** - Method in class `javax.media.jai.RenderableOp`  
Returns one of the node's parameters, as an `int`.

**getIntParameter(String)** - Method in class `javax.media.jai.ParameterBlockJAI`  
A convenience method to return a parameter as an `int`.

**getIter()** - Method in class `javax.media.jai.ROI`  
Get the iterator, construct it if need be.

**getKernelData()** - Method in class `javax.media.jai.KernelJAI`  
Returns a copy of the kernel data in row-major format.

**getLeftPadding()** - Method in class `javax.media.jai.Interpolation`  
Returns the number of samples required to the left of the center.

**getLeftPadding()** - Method in class `javax.media.jai.WarpOpImage`  
Returns the number of samples required to the left of the center.

**getLeftPadding()** - Method in class `javax.media.jai.AreaOpImage`  
Returns the number of pixels needed to the left of the central pixel.

**getLeftPadding()** - Method in class `javax.media.jai.KernelJAI`  
Returns the number of pixels required to the left of the key element.

**getLongParameter(int)** - Method in class `javax.media.jai.RenderedOp`  
Returns the specified parameter stored in the `ParameterBlock` of this node as a `long`.

**getLongParameter(int)** - Method in class `javax.media.jai.RenderableOp`  
Returns one of the node's parameters, as a `long`.

**getLongParameter(String)** - Method in class `javax.media.jai.ParameterBlockJAI`  
A convenience method to return a parameter as a `long`.

**getLowValue()** - Method in class `javax.media.jai.Histogram`  
Returns the lowest value checked for all bands.

**getLowValue(int)** - Method in class `javax.media.jai.Histogram`  
Returns the lowest value checked for a specified band.

**getMatrix(double[])** - Method in class `javax.media.jai.PerspectiveTransform`  
Retrieves the 9 specifiable values in the 3x3 affine transformation matrix into an array of double precision values.

**getMatrix(double[][])** - Method in class `javax.media.jai.PerspectiveTransform`  
Retrieves the 9 specifiable values in the 3x3 affine transformation matrix into a 2-dimensional array of double precision values.

**getMaximumSize()** - Method in class `javax.media.jai.widget.ImageCanvas`

**getMaxTileX()** - Method in class `javax.media.jai.PlanarImage`  
Returns the horizontal index of the rightmost column of tiles.

**getMaxTileY()** - Method in class `javax.media.jai.PlanarImage`  
Returns the vertical index of the bottom row of tiles.

**getMaxX()** - Method in class `javax.media.jai.PlanarImage`  
Returns the X coordinate of the column immediately to the right of the rightmost column of the image.

**getMaxX()** - Method in class `javax.media.jai.RenderedOp`  
Renders the node if it has not already been rendered, and returns the X coordinate of the column immediately to the right of the rightmost column of the rendered image.

**getMaxX()** - Method in class `javax.media.jai.MultiResolutionRenderableImage`  
Returns the floating-point max X coordinate of the `RenderableImage`.

**getMaxX()** - Method in class `javax.media.jai.RemoteImage`  
Returns the X coordinate of the column immediately to the right of the rightmost column of the image.

**getMaxY()** - Method in class `javax.media.jai.PlanarImage`  
Returns the Y coordinate of the row immediately below the bottom row of the image.

**getMaxY()** - Method in class `javax.media.jai.RenderedOp`  
Renders the node if it has not already been rendered, and returns the Y coordinate of the row immediately below the bottom row of the rendered image.

**getMaxY()** - Method in class `javax.media.jai.MultiResolutionRenderableImage`  
Returns the floating-point max Y coordinate of the `RenderableImage`.

**getMaxY()** - Method in class `javax.media.jai.RemoteImage`  
Returns the Y coordinate of the row immediately below the bottom row of the image.

**getMemoryCapacity()** - Method in interface `javax.media.jai.TileCache`  
Returns the memory capacity in bytes.

**getMinimumSize()** - Method in class `javax.media.jai.widget.ImageCanvas`

**getMinNumParameters()** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns the minimum number of parameters must be supplied in the `ParameterBlock`.

**getMinTileX()** - Method in class javax.media.jai.PlanarImage  
Returns the horizontal index of the leftmost column of tiles.

**getMinTileY()** - Method in class javax.media.jai.PlanarImage  
Returns the vertical index of the uppermost row of tiles.

**getMinX()** - Method in class javax.media.jai.PlanarImage  
Returns the X coordinate of the leftmost column of the image.

**getMinX()** - Method in class javax.media.jai.RenderedOp  
Renders the node if it has not already been rendered, and returns the X coordinate of the leftmost column of the rendered image.

**getMinX()** - Method in class javax.media.jai.RenderableOp  
Gets the minimum X coordinate of the rendering-independent image data.

**getMinX()** - Method in class javax.media.jai.RenderableImageAdapter  
Gets the minimum X coordinate of the rendering-independent image.

**getMinX()** - Method in class javax.media.jai.MultiResolutionRenderableImage  
Returns the floating-point min X coordinate of the `RenderableImage`.

**getMinX()** - Method in class javax.media.jai.RemoteImage  
Returns the X coordinate of the leftmost column of the image.

**getMinX()** - Method in class javax.media.jai.RenderableGraphics

**getMinX(RenderedImage)** - Method in class javax.media.jai.ImageLayout  
Returns the value of minX if it is valid, and otherwise returns the value from the supplied `RenderedImage`.

**getMinY()** - Method in class javax.media.jai.PlanarImage  
Returns the Y coordinate of the uppermost row of the image.

**getMinY()** - Method in class javax.media.jai.RenderedOp  
Renders the node if it has not already been rendered, and returns the X coordinate of the uppermost row of the rendered image.

**getMinY()** - Method in class javax.media.jai.RenderableOp  
Gets the minimum Y coordinate of the rendering-independent image data.

**getMinY()** - Method in class javax.media.jai.RenderableImageAdapter  
Gets the minimum Y coordinate of the rendering-independent image.

**getMinY()** - Method in class javax.media.jai.MultiResolutionRenderableImage  
Returns the floating-point min Y coordinate of the `RenderableImage`.

**getMinY()** - Method in class javax.media.jai.RemoteImage  
Returns the Y coordinate of the uppermost row of the image.

**getMinY()** - Method in class javax.media.jai.RenderableGraphics

**getMinY(RenderedImage)** - Method in class javax.media.jai.ImageLayout  
Returns the value of minY if it is valid, and otherwise returns the value from the supplied `RenderedImage`.

**getModificationTime()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns the modification time to be stored with this image.

**getMultipliers()** - Method in class javax.media.jai.ColorCube  
Get the multipliers as an array.

**getName()** - Method in interface javax.media.jai.OperationDescriptor  
Returns the name of this operation; this is the same as the `GlobalName` value in the resources.

**getName()** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns the name of this operation; this is the same as the `GlobalName` value in the resources and is visible to all.

**getName()** - Method in class javax.media.jai.PartialOrderNode  
Returns the name of the Object represented by this node.

**getNeighbors()** - Method in class javax.media.jai.PartialOrderNode  
Returns the neighbors of this node as an enumeration.

**getNodeSource(int)** - Method in class javax.media.jai.RenderedOp

**getNumBands()** - Method in class javax.media.jai.RasterFormatTag  
Returns the number of bands in the underlying Raster

**getNumBands()** - Method in class javax.media.jai.LookupTableJAI  
Returns the number of bands of the table.

**getNumBands()** - Method in class javax.media.jai.Histogram  
Returns the number of bands of the histogram.

**getNumBands()** - Method in class javax.media.jai.RasterAccessor  
Returns the numBands of the presented area.

**getNumBins()** - Method in class javax.media.jai.Histogram  
Returns the number of bins of the histogram for all bands.

**getNumBins(int)** - Method in class javax.media.jai.Histogram  
Returns the number of bins of the histogram for a specified band.

**getNumDirectories(SeekableStream)** - Static method in class com.sun.media.jai.codec.TIFFDirectory  
Returns the number of image directories (subimages) stored in a given TIFF file, represented by a `SeekableStream`.

**getNumElements()** - Method in interface javax.media.jai.ImageFunction  
Returns the number of elements per value at each position.

**getNumElements()** - Method in class javax.media.jai.IntegerSequence  
Returns the number of elements contained within this `IntegerSequence`.

**getNumEntries()** - Method in class javax.media.jai.LookupTableJAI  
Returns the number of entries per band of the table.

**getNumEntries()** - Method in class com.sun.media.jai.codec.TIFFDirectory  
Returns the number of directory entries.

**getNumHeaderBytes()** - Method in class com.sun.media.jai.codec.ImageCodec  
Returns the number of bytes of header needed to recognize the format, or 0 if an arbitrary number of bytes may be needed.

**getNumPages()** - Method in class com.sun.media.jai.codec.ImageDecoderImpl  
Returns the number of pages present in the current stream.

**getNumPages()** - Method in interface com.sun.media.jai.codec.ImageDecoder  
Returns the number of pages present in the current stream.

**getNumParameters()** - Method in class javax.media.jai.RenderedOp  
Returns the number of parameters stored in the `ParameterBlock` of this node.

**getNumParameters()** - Method in interface javax.media.jai.OperationDescriptor  
Returns the number of parameters (not including the sources) required by this operation.

**getNumParameters()** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns the number of parameters (not including sources) required by this operation.

**getNumPrivateChunks()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns the number of private chunks to be written to the output file.

**getNumRetries()** - Method in class javax.media.jai.RemoteImage  
Gets the number of retries.

**getNumSources()** - Method in class javax.media.jai.PlanarImage  
Returns the number of `PlanarImage` sources.

**getNumSources()** - Method in class javax.media.jai.RenderedOp  
Returns the number of sources stored in the `ParameterBlock` of this node.

**getNumSources()** - Method in interface javax.media.jai.OperationDescriptor  
Returns the number of sources required by this operation.

**getNumSources()** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns the number of sources required by this operation.

**getNumXTiles()** - Method in class javax.media.jai.PlanarImage  
Returns the number of tiles along the tile grid in the horizontal direction.

**getNumYTiles()** - Method in class javax.media.jai.PlanarImage  
Returns the number of tiles along the tile grid in the vertical direction.

**getObjectParameter(int)** - Method in class javax.media.jai.RenderedOp  
Returns the specified parameter stored in the `ParameterBlock` of this node as an `Object`.

**getObjectParameter(int)** - Method in class javax.media.jai.RenderableOp  
Returns one of the node's parameters, as an `Object`.

**getObjectParameter(String)** - Method in class javax.media.jai.ParameterBlockJAI  
Gets a named parameter as an `Object`.

**getOffset()** - Method in class javax.media.jai.LookupTableJAI  
Returns the index offset of entry 0 for the default band.

**getOffset(int)** - Method in class javax.media.jai.LookupTableJAI  
Returns the index offset of entry 0 for a specific band.

**getOffsetForBand(int)** - Method in class javax.media.jai.RasterAccessor  
Returns the offset of a specified band's sample from any pixel offset.

**getOffsets()** - Method in class javax.media.jai.LookupTableJAI  
Returns the index offsets of entry 0 for all bands.

**getOffsetsForBands()** - Method in class javax.media.jai.RasterAccessor  
Returns the offset of all band's samples from any pixel offset.

**getOperationComputeType()** - Method in class javax.media.jai.OpImage  
Returns one of `OP_COMPUTE_BOUND`, `OP_IO_BOUND`, or `OP_NETWORK_BOUND` to indicate how the operation is likely to spend its time.

**getOperationComputeType()** - Method in class javax.media.jai.NullOpImage  
Returns one of `OP_COMPUTE_BOUND`, `OP_IO_BOUND`, or `OP_NETWORK_BOUND` to indicate how the operation is likely to spend its time.

**getOperationDescriptor()** - Method in class javax.media.jai.ParameterBlockJAI  
Returns the `OperationDescriptor` associated with this `ParameterBlockJAI`.

**getOperationDescriptor(String)** - Method in class javax.media.jai.OperationRegistry  
Returns the `OperationDescriptor` that is currently registered under the given name, or null if none exists.

**getOperationDescriptors()** - Method in class javax.media.jai.OperationRegistry  
Returns a `Vector` of all currently registered `OperationDescriptors`.

**getOperationName()** - Method in class javax.media.jai.RenderedOp  
Returns the name of the operation this node represents as a `String`.

**getOperationName()** - Method in class javax.media.jai.RenderableOp  
Returns the name of the operation this node represents as a `String`.

**getOperationName()** - Method in class javax.media.jai.CollectionOp  
Returns the name of the operation this node represents as a `String`.

**getOperationNames()** - Method in class javax.media.jai.OperationRegistry  
Returns a list of names under which all the `OperationDescriptors` in the registry are registered.

**getOperationRegistry()** - Method in class javax.media.jai.JAI  
Returns the `OperationRegistry` being used by this JAI instance.

**getOrderedCIFList(String, String)** - Method in class javax.media.jai.OperationRegistry  
Returns a list of the CIFs of a product registered under a particular `OperationDescriptor`, in an ordering that satisfies all of the pairwise preferences that have been set.

**getOrderedOperationList()** - Method in class javax.media.jai.ProductOperationGraph  
Performs a topological sort on the set of RIFs.

**getOrderedOperationList(String)** - Method in class javax.media.jai.OperationGraph  
Returns an ordered list of the specified imageFactory

**getOrderedProductList(String)** - Method in class javax.media.jai.OperationRegistry  
Returns a list of the products registered under a particular `OperationDescriptor`, in an ordering that satisfies all of the pairwise preferences that have been set.

**getOrderedRIFList(String, String)** - Method in class javax.media.jai.OperationRegistry  
Returns a list of the RIFs of a product registered under a particular `OperationDescriptor`, in an ordering that satisfies all of the pairwise preferences that have been set.

**getOutput8BitGray()** - Method in class com.sun.media.jai.codec.PNGDecodeParam  
Returns the current value of the 8-bit gray output parameter.

**getOutputStream()** - Method in class com.sun.media.jai.codec.ImageEncoderImpl  
Returns the `OutputStream` associated with this `ImageEncoder`.

**getOutputStream()** - Method in interface com.sun.media.jai.codec.ImageEncoder  
Returns the `OutputStream` associated with this `ImageEncoder`.

**getPaint()** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**getPaint()** - Method in class javax.media.jai.TiledImageGraphics

**getPaint()** - Method in class javax.media.jai.RenderableGraphics

**getPalette()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Palette  
Returns the current RGB palette.

**getPaletteHistogram()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns the palette histogram to be stored with this image.

**getPaletteTransparency()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Palette  
Returns the alpha values associated with each palette entry.

**getParam()** - Method in class com.sun.media.jai.codec.ImageDecoderImpl  
Returns the current parameters as an instance of the `ImageDecodeParam` interface.

**getParam()** - Method in class com.sun.media.jai.codec.ImageEncoderImpl  
Returns the current parameters as an instance of the `ImageEncodeParam` interface.

**getParam()** - Method in interface com.sun.media.jai.codec.ImageDecoder  
Returns the current parameters as an instance of the `ImageDecodeParam` interface.

**getParam()** - Method in interface com.sun.media.jai.codec.ImageEncoder  
Returns the current parameters as an instance of the `ImageEncodeParam` interface.

**getParamClasses()** - Method in interface javax.media.jai.OperationDescriptor  
Returns an array of `Classes` that describe the types of parameters required by this operation.

**getParamClasses()** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns the parameter class types of this operation.

**getParamDefaults()** - Method in interface javax.media.jai.OperationDescriptor  
Returns an array of `Objects` that define the default values of the parameters for this operation.

**getParamDefaults()** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns the default values of the parameters for this operation.

**getParamDefaultValue(int)** - Method in interface javax.media.jai.OperationDescriptor  
Returns the default value of a specified parameter.

**getParamDefaultValue(int)** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns the default value of specified parameter.

**getParameterBlock()** - Method in class javax.media.jai.RenderedOp  
Returns the `ParameterBlock` of this node.

**getParameterBlock()** - Method in class javax.media.jai.RenderableOp  
Returns the `ParameterBlock` of this node.

**getParameterBlock()** - Method in class javax.media.jai.CollectionOp  
Returns the `ParameterBlock` of this node.

**getParameters()** - Method in class javax.media.jai.RenderedOp  
Returns the parameters stored in the `ParameterBlock` of this node.

**getParamMaxValue(int)** - Method in interface javax.media.jai.OperationDescriptor  
Returns the maximum legal value of a specified numeric parameter for this operation.

**getParamMaxValue(int)** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns the maximum legal value of a specified numeric parameter for this operation.

**getParamMaxValue(int)** - Method in class javax.media.jai.operator.BorderDescriptor  
Returns the maximum legal value of a specified numeric parameter for this operation.

**getParamMaxValue(int)** - Method in class javax.media.jai.operator.CompositeDescriptor  
Returns the maximum legal value of a specified numeric parameter for this operation.

**getParamMaxValue(int)** - Method in class javax.media.jai.operator.FormatDescriptor  
Returns the maximum legal value of a specified numeric parameter for this operation.

**getParamMaxValue(int)** - Method in class javax.media.jai.operator.TransposeDescriptor  
Returns the maximum legal value of a specified numeric parameter for this operation.

**getParamMaxValue(int)** - Method in class javax.media.jai.operator.IIPDescriptor  
Returns the maximum legal value of a specified numeric parameter for this operation.

**getParamMaxValue(int)** - Method in class javax.media.jai.operator.MedianFilterDescriptor  
Returns the maximum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in interface javax.media.jai.OperationDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.BorderDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.CompositeDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.FormatDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.ExtremaDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.MeanDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.BoxFilterDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.IIPResolutionDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.ConstantDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.TransposeDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.PatternDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.HistogramDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.IIPDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.MedianFilterDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamMinValue(int)** - Method in class javax.media.jai.operator.ScaleDescriptor  
Returns the minimum legal value of a specified numeric parameter for this operation.

**getParamNames()** - Method in interface javax.media.jai.OperationDescriptor  
Returns an array of `Strings` that are the localized parameter names of this operation.

**getParamNames()** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns the localized parameter names of this operation.

**getPerformGammaCorrection()** - Method in class com.sun.media.jai.codec.PNGDecodeParam  
Returns `true` if gamma correction is to be performed on the image data.

**getPhysicalDimension()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns the physical dimension information to be stored with this image.

**getPixel(double[])** - Method in interface javax.media.jai.iterator.RectIter  
Returns the samples of the current pixel from the image in an array of `double`.

**getPixel(float[])** - Method in interface javax.media.jai.iterator.RectIter  
Returns the samples of the current pixel from the image in an array of `float`.

**getPixel(int[])** - Method in interface javax.media.jai.iterator.RectIter  
Returns the samples of the current pixel from the image in an array of `int`.

**getPixel(int, int, double[])** - Method in interface javax.media.jai.iterator.RandomIter  
Returns the samples of the specified pixel from the image in an array of `double`.

**getPixel(int, int, float[])** - Method in interface javax.media.jai.iterator.RandomIter  
Returns the samples of the specified pixel from the image in an array of float.

**getPixel(int, int, int[])** - Method in interface javax.media.jai.iterator.RandomIter  
Returns the samples of the specified pixel from the image in an array of int.

**getPixels(int, int, int, double[], DataBuffer)** - Method in class javax.media.jai.ComponentSampleModelJAI  
Returns all samples for a rectangle of pixels in a double array, one sample per array element.

**getPixelStride()** - Method in class javax.media.jai.RasterFormatTag  
Returns the pixelStride of the underlying Raster

**getPixelStride()** - Method in class javax.media.jai.RasterAccessor  
Returns the pixelStride for the image data.

**getPostScaleX()** - Method in class javax.media.jai.WarpPolynomial  
Returns the scaling factor applied to the result of the X polynomial.

**getPostScaleY()** - Method in class javax.media.jai.WarpPolynomial  
Returns the scaling factor applied to the result of the Y polynomial.

**getPrecisionBits()** - Method in class javax.media.jai.InterpolationTable  
Returns the number of bits of fractional precision used to store the fixed-point table entries.

**getPreferredSize()** - Method in class javax.media.jai.widget.ImageCanvas

**getPreferredSize()** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Called by the AWT when instantiating the component.

**getPreScaleX()** - Method in class javax.media.jai.WarpPolynomial  
Returns the scaling factor applied to input (dest) X coordinates.

**getPreScaleY()** - Method in class javax.media.jai.WarpPolynomial  
Returns the scaling factor applied to input (dest) Y coordinates.

**getPrivateChunkData(int)** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns the data associated of the private chunk at a given index, as an array of bytes.

**getPrivateChunkType(int)** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns the type of the private chunk at a given index, as a 4-character String.

**getProductPreferences(String)** - Method in class javax.media.jai.OperationRegistry  
Returns a list of the pairwise product preferences under a particular OperationDescriptor.

**getProperties()** - Method in class javax.media.jai.PlanarImage  
Returns the internal Hashtable containing the image properties.

**getProperties()** - Method in class javax.media.jai.NullOpImage  
Returns the properties from the source image.

**getProperty(String)** - Method in class javax.media.jai.PlanarImage  
Gets a property from the property set of this image.

**getProperty(String)** - Method in class javax.media.jai.RenderedOp  
Returns the property associated with the specified property name, or java.awt.Image.UndefinedProperty if the specified property is not set on the image.

**getProperty(String)** - Method in class javax.media.jai.ImageMIPMap  
Returns the specified property.

**getProperty(String)** - Method in class javax.media.jai.RenderableOp  
Gets a property from the property set of this image.

**getProperty(String)** - Method in class javax.media.jai.RenderableImageAdapter  
Gets a property from the property set of this image.

**getProperty(String)** - Method in class javax.media.jai.MultiResolutionRenderableImage  
Gets a property from the property set of this image.

**getProperty(String)** - Method in class javax.media.jai.CollectionImage  
Returns the specified property.

**getProperty(String)** - Method in class javax.media.jai.RemoteImage  
Gets a property from the property set of this image.

**getProperty(String)** - Method in class javax.media.jai.NullOpImage  
Retrieves a property from the source image by name or java.awt.Image.UndefinedProperty if the property with the specified name is not defined.

**getProperty(String)** - Method in class javax.media.jai.RenderedImageAdapter  
Forwards call to the true source.

**getProperty(String)** - Method in class javax.media.jai.PropertySourceImpl  
Returns the value of a property.

**getProperty(String)** - Method in class javax.media.jai.StatisticsOpImage  
Returns one of the available statistics as a property.

**getProperty(String)** - Method in class javax.media.jai.RenderableGraphics

**getProperty(String)** - Method in interface javax.media.jai.PropertySource  
Returns the value of a property.

**getProperty(String, Collection)** - Method in class javax.media.jai.CollectionImage  
Returns the specified property.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.PropertyGeneratorFromSource

**getProperty(String, RenderableOp)** - Method in interface javax.media.jai.PropertyGenerator  
Computes the value of a property relative to an environment of pre-existing properties emitted by the sources of a RenderableOp, and the parameters of that operation.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.CopyPropertyGenerator

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.PolarToComplexPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.ImageFunctionPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.WarpPropertyGenerator  
Returns null.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.MagnitudePropertyGenerator  
Returns the specified property.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.PhasePropertyGenerator  
Returns the specified property.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.MultiplyComplexPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.TransposePropertyGenerator  
Returns null.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.TranslatePropertyGenerator  
Returns null.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.DFTPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.ShearPropertyGenerator  
Returns null.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.AffinePropertyGenerator  
Returns null.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.RotatePropertyGenerator  
Returns null.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.IDFTPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.MagnitudeSquaredPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.ConjugatePropertyGenerator  
Returns the specified property.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.DivideComplexPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderableOp)** - Method in class javax.media.jai.operator.ScalePropertyGenerator  
Returns null.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.PropertyGeneratorFromSource

**getProperty(String, RenderedOp)** - Method in interface javax.media.jai.PropertyGenerator  
Computes the value of a property relative to an environment of pre-existing properties emitted by the sources of a RenderedOp, and the parameters of that operation.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.CopyPropertyGenerator

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.PolarToComplexPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.ImageFunctionPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.WarpPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.MagnitudePropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.PhasePropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.MultiplyComplexPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.TransposePropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.TranslatePropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.DFTPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.ShearPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.AffinePropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.RotatePropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.IDFTPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.MagnitudeSquaredPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.ConjugatePropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.DivideComplexPropertyGenerator  
Returns the specified property.

**getProperty(String, RenderedOp)** - Method in class javax.media.jai.operator.ScalePropertyGenerator  
Returns the specified property.

**getPropertyGenerators()** - Method in interface javax.media.jai.OperationDescriptor  
Returns an array of `PropertyGenerators` implementing the property inheritance for this operation.

**getPropertyGenerators()** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns an array of `PropertyGenerators` implementing the property inheritance for this operation.

**getPropertyGenerators()** - Method in class javax.media.jai.operator.PolarToComplexDescriptor  
Returns an array of `PropertyGenerators` implementing property inheritance for the "Conjugate" operation.

**getPropertyGenerators()** - Method in class javax.media.jai.operator.ImageFunctionDescriptor  
Returns an array of `PropertyGenerators` implementing property inheritance for the "ImageFunction" operation.

**getPropertyGenerators()** - Method in class javax.media.jai.operator.WarpDescriptor  
Returns an array of `PropertyGenerators` implementing property inheritance for the "Warp" operation.

**getPropertyGenerators()** - Method in class javax.media.jai.operator.GradientMagnitudeDescriptor  
Returns an array of

## H

**hasAlpha** - Variable in class javax.media.jai.FloatDoubleColorModel

**hasCompatibleSampleModel(PlanarImage)** - Method in class javax.media.jai.PointOpImage

**hasExtender(int)** - Method in class javax.media.jai.OpImage  
Indicates whether the source with the given index has a `BorderExtender`.

**hashNames()** - Method in class javax.media.jai.PropertySourceImpl

**hashNames(String)** - Method in class javax.media.jai.OperationRegistry

**hasMoreElements()** - Method in class javax.media.jai.IntegerSequence  
Returns true if more elements are available to be iterated over.

**hasTile(int, int)** - Method in class javax.media.jai.Snapshot  
Returns true if this `Snapshot` already stores a version of a specified tile.

**hasTileWriters()** - Method in class javax.media.jai.WritableRenderedImageAdapter  
Return whether any tile is checked out for writing.

**hasTileWriters()** - Method in class javax.media.jai.TiledImage  
Returns true if any tile is being held by a writer, false otherwise.

**height** - Variable in class javax.media.jai.ImageLayout  
The image's height.

**height** - Variable in class javax.media.jai.PlanarImage  
The image's height in pixels.

**height** - Variable in class javax.media.jai.Interpolation  
The height of the interpolation kernel in pixels.

**height** - Variable in class javax.media.jai.MultiResolutionRenderableImage  
The height in `Renderable` coordinates.

**height** - Variable in class javax.media.jai.KernelJAI  
The height of the kernel.

**HEIGHT\_MASK** - Static variable in class javax.media.jai.ImageLayout  
A bitmask to specify the validity of height.

**highestImage** - Variable in class javax.media.jai.ImageMIPMap  
The image with the highest resolution.

**highValue** - Variable in class javax.media.jai.Histogram  
The highest pixel value of the image checked for each band.

**HINT\_BORDER\_EXTENDER** - Static variable in class javax.media.jai.JAI

**HINT\_IMAGE\_LAYOUT** - Static variable in class javax.media.jai.JAI

**HINT\_INTERPOLATION** - Static variable in class javax.media.jai.JAI

**HINT\_OPERATION\_BOUND** - Static variable in class javax.media.jai.JAI

**HINT\_OPERATION\_REGISTRY** - Static variable in class javax.media.jai.JAI

**HINT\_TILE\_CACHE** - Static variable in class javax.media.jai.JAI

**hints** - Variable in class javax.media.jai.CollectionOp

The rendering hints to use for this operation.

**Histogram** - class javax.media.jai.Histogram.

An object for accumulating histogram information on an image.

**Histogram(int[], double[], double[])** - Constructor for class javax.media.jai.Histogram

Constructs a Histogram that may be used to accumulate data within a given range for each band of an image.

**HistogramDescriptor** - class javax.media.jai.operator.HistogramDescriptor.

An OperationDescriptor describing the "Histogram" operation.

**HistogramDescriptor()** - Constructor for class javax.media.jai.operator.HistogramDescriptor

Constructor.

**hit(Rectangle, Shape, boolean)** - Method in class javax.media.jai.GraphicsJAI

See comments in java.awt.Graphics2D.

**hit(Rectangle, Shape, boolean)** - Method in class javax.media.jai.TiledImageGraphics

**hit(Rectangle, Shape, boolean)** - Method in class javax.media.jai.RenderableGraphics

**hSamp** - Variable in class com.sun.media.jai.codec.JPEGEncodeParam

---

## I

**i** - Variable in class javax.media.jai.ROIShape.PolyShape.PolyEdge

The edge number: edge i goes from vertex i to vertex i+1.

**iArray** - Variable in class javax.media.jai.IntegerSequence

The array storing the unsorted integer values.

**ic** - Variable in class javax.media.jai.widget.ScrollingImagePanel

The ImageCanvas we are controlling.

**ICCProfileData** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**ICCProfileDataSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**id** - Variable in class javax.media.jai.RemoteImage

**IDCTDescriptor** - class javax.media.jai.operator.IDCTDescriptor.

An OperationDescriptor describing the "IDCT" operation.

**IDCTDescriptor()** - Constructor for class javax.media.jai.operator.IDCTDescriptor

Constructor.

**IDFTDescriptor** - class javax.media.jai.operator.IDFTDescriptor.

An OperationDescriptor describing the "IDFT" operation.

**IDFTDescriptor()** - Constructor for class javax.media.jai.operator.IDFTDescriptor

Constructor.

**IDFTPropertyGenerator** - class javax.media.jai.operator.IDFTPropertyGenerator.

This property generator computes the properties for the operation "IDFT" dynamically.

**IDFTPropertyGenerator()** - Constructor for class javax.media.jai.operator.IDFTPropertyGenerator

Constructor.

**IIPDescriptor** - class javax.media.jai.operator.IIPDescriptor.

An OperationDescriptor describing the "IIP" operation.

**IIPDescriptor()** - Constructor for class javax.media.jai.operator.IIPDescriptor

Constructor.

**IIPResolutionDescriptor** - class javax.media.jai.operator.IIPResolutionDescriptor.

An OperationDescriptor describing the "IIPResolution" operation.

**IIPResolutionDescriptor()** - Constructor for class javax.media.jai.operator.IIPResolutionDescriptor

Constructor.

**im** - Variable in class javax.media.jai.RenderableImageAdapter

A reference to the external RenderableImage.

**im** - Variable in class javax.media.jai.CopyPropertyGenerator

**im** - Variable in class javax.media.jai.widget.ImageCanvas  
The source RenderedImage.

**im** - Variable in class javax.media.jai.widget.ScrollingImagePanel  
The RenderedImage displayed by the ImageCanvas.

**image** - Variable in class javax.media.jai.SequentialImage  
The image.

**image** - Variable in class javax.media.jai.CoordinateImage  
The image.

**imageBounds** - Variable in class javax.media.jai.RemoteImage

**imageBounds** - Variable in class javax.media.jai.TiledImage

**ImageCanvas** - class javax.media.jai.widget.ImageCanvas.  
A simple output widget for a RenderedImage.

**ImageCanvas(RenderedImage)** - Constructor for class javax.media.jai.widget.ImageCanvas  
Constructs an ImageCanvas to display a RenderedImage.

**ImageCanvas(RenderedImage, boolean)** - Constructor for class javax.media.jai.widget.ImageCanvas  
Constructs an ImageCanvas to display a RenderedImage.

**ImageCodec** - class com.sun.media.jai.codec.ImageCodec.  
An abstract class allowing the creation of image decoders and encoders.

**ImageCodec()** - Constructor for class com.sun.media.jai.codec.ImageCodec  
Allow only subclasses to instantiate this class.

**imageCollection** - Variable in class javax.media.jai.CollectionImage  
A collection of objects.

**ImageDecodeParam** - interface com.sun.media.jai.codec.ImageDecodeParam.  
An empty (marker) interface to be implemented by all image decoder parameter classes.

**ImageDecoder** - interface com.sun.media.jai.codec.ImageDecoder.  
An interface describing objects that transform an InputStream into a BufferedImage or Raster.

**ImageDecoderImpl** - class com.sun.media.jai.codec.ImageDecoderImpl.  
A partial implementation of the ImageDecoder interface useful for subclassing.

**ImageDecoderImpl(InputStream, ImageDecodeParam)** - Constructor for class com.sun.media.jai.codec.ImageDecoderImpl  
Constructs an ImageDecoderImpl with a given InputStream and ImageDecodeParam instance.

**ImageDecoderImpl(SeekableStream, ImageDecodeParam)** - Constructor for class com.sun.media.jai.codec.ImageDecoderImpl  
Constructs an ImageDecoderImpl with a given SeekableStream and ImageDecodeParam instance.

**ImageEncodeParam** - interface com.sun.media.jai.codec.ImageEncodeParam.  
An empty (marker) interface to be implemented by all image encoder parameter classes.

**ImageEncoder** - interface com.sun.media.jai.codec.ImageEncoder.  
An interface describing objects that transform a BufferedImage or Raster into an OutputStream.

**ImageEncoderImpl** - class com.sun.media.jai.codec.ImageEncoderImpl.  
A partial implementation of the ImageEncoder interface useful for subclassing.

**ImageEncoderImpl(OutputStream, ImageEncodeParam)** - Constructor for class com.sun.media.jai.codec.ImageEncoderImpl  
Constructs an ImageEncoderImpl with a given OutputStream and ImageEncoderParam instance.

**ImageFunction** - interface javax.media.jai.ImageFunction.  
ImageFunction is a common interface for vector-valued functions which are to be evaluated at positions in the X-Y coordinate system.

**ImageFunctionDescriptor** - class javax.media.jai.operator.ImageFunctionDescriptor.  
An OperationDescriptor describing the "ImageFunction" operation.

**ImageFunctionDescriptor()** - Constructor for class javax.media.jai.operator.ImageFunctionDescriptor  
Constructor.

**ImageFunctionPropertyGenerator** - class javax.media.jai.operator.ImageFunctionPropertyGenerator.  
This property generator computes the properties for the operation "ImageFunction" dynamically.

**ImageFunctionPropertyGenerator()** - Constructor for class javax.media.jai.operator.ImageFunctionPropertyGenerator  
Constructor.

**ImageJAI** - interface javax.media.jai.ImageJAI.  
An interface implemented by all JAI image classes.

**ImageLayout** - class javax.media.jai.ImageLayout.  
A class describing the desired layout of an OpImage.

**ImageLayout()** - Constructor for class javax.media.jai.ImageLayout  
Constructs an ImageLayout with no parameters set.

**ImageLayout(int, int, int, int)** - Constructor for class javax.media.jai.ImageLayout  
Constructs an ImageLayout with only the image dimension parameters set.

**ImageLayout(int, int, int, int, int, int, int, int, SampleModel, ColorModel)** - Constructor for class javax.media.jai.ImageLayout  
Constructs an ImageLayout with all its parameters set.

**ImageLayout(int, int, int, int, SampleModel, ColorModel)** - Constructor for class javax.media.jai.ImageLayout  
Constructs an ImageLayout with its tile grid layout, SampleModel, and ColorModel parameters set.

**ImageLayout(RenderedImage)** - Constructor for class javax.media.jai.ImageLayout  
Constructs an ImageLayout with all its parameters set to equal those of a given RenderedImage.

**ImageMIPMap** - class javax.media.jai.ImageMIPMap.  
A class implementing the "MIP map" operation on a RenderedImage.

**ImageMIPMap()** - Constructor for class javax.media.jai.ImageMIPMap  
The default constructor.

**ImageMIPMap(RenderedImage, AffineTransform, Interpolation)** - Constructor for class javax.media.jai.ImageMIPMap  
Constructor.

**ImageMIPMap(RenderedImage, RenderedOp)** - Constructor for class javax.media.jai.ImageMIPMap  
Constructor.

**ImageMIPMap(RenderedOp)** - Constructor for class javax.media.jai.ImageMIPMap  
Constructs a new ImageMIPMap from a RenderedOp chain.

**ImagePyramid** - class javax.media.jai.ImagePyramid.  
A class implementing the "Pyramid" operation on a RenderedImage.

**ImagePyramid()** - Constructor for class javax.media.jai.ImagePyramid  
The default constructor.

**ImagePyramid(RenderedImage, RenderedOp, RenderedOp, RenderedOp, RenderedOp)** - Constructor for class javax.media.jai.ImagePyramid  
Constructor.

**ImagePyramid(RenderedOp, RenderedOp, RenderedOp, RenderedOp)** - Constructor for class javax.media.jai.ImagePyramid  
Constructor.

**ImageSequence** - class javax.media.jai.ImageSequence.  
A class representing a sequence of images, each associated with a time stamp and a camera position.

**ImageSequence()** - Constructor for class javax.media.jai.ImageSequence  
The default constructor.

**ImageSequence(Collection)** - Constructor for class javax.media.jai.ImageSequence  
Constructs a class that represents a sequence of images.

**ImageStack** - class javax.media.jai.ImageStack.  
A class representing a stack of images, each associated with a spatial orientation defined in a common coordinate system.

**ImageStack()** - Constructor for class javax.media.jai.ImageStack  
The default constructor.

**ImageStack(Collection)** - Constructor for class javax.media.jai.ImageStack  
Constructor.

**imHeight** - Variable in class javax.media.jai.widget.ImageCanvas

**imWidth** - Variable in class javax.media.jai.widget.ImageCanvas

**incrementCopyInDegree()** - Method in class javax.media.jai.PartialOrderNode  
Increments the copy-in-degree of a node.

**incrementInDegree()** - Method in class javax.media.jai.PartialOrderNode  
Increments the in-degree of a node.

**inDegree** - Variable in class javax.media.jai.PartialOrderNode  
The in-degree of the node.

**indexOf(String)** - Method in class javax.media.jai.ParameterBlockJAI  
Returns the index of a named parameter within the list of parameters, starting with 0.

**indexTable** - Variable in class javax.media.jai.ParameterBlockJAI  
A Hashtable mapping parameter names to their index.

**initFields(int, int[])** - Method in class javax.media.jai.ColorCube  
Initialize the fields of a ColorCube.

**initialize()** - Method in class javax.media.jai.widget.ImageCanvas  
Initializes the ImageCanvas.

**initialize()** - Method in class com.sun.media.jai.codec.TIFFDirectory

**initialize(BorderExtender[], ImageLayout, boolean)** - Method in class javax.media.jai.OpImage

**initialize(int, int, int, int, int, int, float[])** - Method in class javax.media.jai.WarpGrid

**initializeFields()** - Method in class javax.media.jai.PointOpImage

**initializeFromStream(InputStream)** - Method in class javax.media.jai.OperationRegistry  
Loads the contents of the OperationRegistry from an InputStream.

**initializeNoSource(ImageLayout)** - Method in class javax.media.jai.OpImage

**initializeRegistry()** - Static method in class javax.media.jai.OperationRegistry  
Initializes the default registry, creating it if necessary.

**initTileGrid(TiledImage)** - Method in class javax.media.jai.TiledImage

**input** - Variable in class com.sun.media.jai.codec.ImageDecoderImpl  
The SeekableStream associated with this ImageEncoder.

**insert(int)** - Method in class javax.media.jai.IntegerSequence  
Inserts an integer into the sequence.

**insideRect** - Variable in class javax.media.jai.ROIShape.PolyShape  
Flag indicating whether the Polygon is inside the supplied clipping Rectangle.

**intArrayToDoubleArray(int[])** - Method in class javax.media.jai.ROIShape.PolyShape  
Convert an array of ints to an array of doubles.

**intDataArrays** - Variable in class javax.media.jai.RasterAccessor  
The image data in a two-dimensional int array.

**IntegerSequence** - class javax.media.jai.IntegerSequence.  
A growable sorted integer set.

**IntegerSequence()** - Constructor for class javax.media.jai.IntegerSequence  
Constructs a sequence that may contain any integer value.

**IntegerSequence(int, int)** - Constructor for class javax.media.jai.IntegerSequence  
Constructs a sequence bounded by an inclusive range of values.

**INTENT\_ABSOLUTE** - Static variable in class com.sun.media.jai.codec.PNGEncodeParam  
Constant for use with the sRGB chunk.

**INTENT\_PERCEPTUAL** - Static variable in class com.sun.media.jai.codec.PNGEncodeParam  
Constant for use with the sRGB chunk.

**INTENT\_RELATIVE** - Static variable in class com.sun.media.jai.codec.PNGEncodeParam  
Constant for use with the sRGB chunk.

**INTENT\_SATURATION** - Static variable in class com.sun.media.jai.codec.PNGEncodeParam  
Constant for use with the sRGB chunk.

**interp** - Variable in class javax.media.jai.WarpOpImage  
The Interpolation object describing the subpixel interpolation method.

**INTERP\_BICUBIC** - Static variable in class javax.media.jai.Interpolation  
A constant specifying interpolation by the InterpolationBicubic class.

**INTERP\_BICUBIC\_2** - Static variable in class javax.media.jai.Interpolation  
A constant specifying interpolation by the InterpolationBicubic2 class.

**INTERP\_BILINEAR** - Static variable in class javax.media.jai.Interpolation  
A constant specifying interpolation by the InterpolationBilinear class.

**INTERP\_NEAREST** - Static variable in class javax.media.jai.Interpolation  
A constant specifying interpolation by the InterpolationNearest class.

**interpolate(double[][], float, float)** - Method in class javax.media.jai.Interpolation  
Performs interpolation on a 2-dimensional array of double samples.

**interpolate(double[][], float, float)** - Method in class javax.media.jai.InterpolationNearest  
Performs interpolation on a two-dimensional array of double samples.

**interpolate(double[][], float, float)** - Method in class javax.media.jai.InterpolationBilinear  
Performs interpolation on a two-dimensional array of double samples.

**interpolate(double, double, double, double, double, double, double, double, double, double, double, double, double, double, double, float, float)** - Method in class javax.media.jai.Interpolation  
Performs interpolation on a 4x4 grid of double samples.

**interpolate(double, double, double, double, double, double, double, double, double, double, double, double, double, double, double, double, double, float, float)** - Method in class javax.media.jai.InterpolationTable  
Performs interpolation on a 4x4 grid of double samples.

**interpolate(double, double, double, double, double, double, double, double, double, double, double, double, double, double, double, double, double, float, float)** - Method in class javax.media.jai.InterpolationNearest  
Performs interpolation on a 4x4 grid of double samples.

**interpolate(double, double, double, double, double, double, double, double, double, double, double, double, double, double, double, double, double, float, float)** - Method in class javax.media.jai.InterpolationBilinear  
Performs interpolation on a 4x4 grid.

**interpolate(double, double, double, double, double, float, float)** - Method in class javax.media.jai.Interpolation  
Performs interpolation on a 2x2 grid of double samples.

**interpolate(double, double, double, double, float, float)** - Method in class javax.media.jai.InterpolationTable  
Performs interpolation on a 2x2 grid of double samples.

**interpolate(double, double, double, double, float, float)** - Method in class javax.media.jai.InterpolationNearest  
Performs interpolation on a 2x2 grid of double samples.

[illegible]

[illegible]

**interpolateV(double, double, double, double, float)** - Method in class javax.media.jai.InterpolationTable  
Performs vertical interpolation on a quadruple of double samples.

**interpolateV(double, double, double, double, float)** - Method in class javax.media.jai.InterpolationBilinear  
Performs vertical interpolation on a vertical quad of double samples.

**interpolateV(double, double, float)** - Method in class javax.media.jai.Interpolation  
Performs vertical interpolation on a pair of double samples.

**interpolateV(double, double, float)** - Method in class javax.media.jai.InterpolationTable  
Performs vertical interpolation on a pair of double samples.

**interpolateV(double, double, float)** - Method in class javax.media.jai.InterpolationNearest  
Performs vertical interpolation on a pair of double samples.

**interpolateV(double, double, float)** - Method in class javax.media.jai.InterpolationBilinear  
Performs vertical interpolation on a vertical pair of double samples.

**interpolateV(float[], float)** - Method in class javax.media.jai.Interpolation  
Performs vertical interpolation on a 1-dimensional array of floating-point samples representing a column of samples.

**interpolateV(float[], float)** - Method in class javax.media.jai.InterpolationTable  
Performs vertical interpolation on a one-dimensional array of floating-point samples representing a column of samples.

**interpolateV(float[], float)** - Method in class javax.media.jai.InterpolationNearest  
Performs vertical interpolation on a one-dimensional array of floating-point samples.

**interpolateV(float[], float)** - Method in class javax.media.jai.InterpolationBilinear  
Performs vertical interpolation on a one-dimensional array of floating-point samples.

**interpolateV(float, float, float)** - Method in class javax.media.jai.Interpolation  
Performs vertical interpolation on a pair of floating-point samples.

**interpolateV(float, float, float)** - Method in class javax.media.jai.InterpolationTable  
Performs vertical interpolation on a pair of floating-point samples.

**interpolateV(float, float, float)** - Method in class javax.media.jai.InterpolationNearest  
Performs vertical interpolation on a pair of floating-point samples.

**interpolateV(float, float, float)** - Method in class javax.media.jai.InterpolationBilinear  
Performs vertical interpolation on a vertical pair of floating-point samples.

**interpolateV(float, float, float, float, float)** - Method in class javax.media.jai.Interpolation  
Performs vertical interpolation on a quadruple of floating-point samples.

**interpolateV(float, float, float, float, float)** - Method in class javax.media.jai.InterpolationTable  
Performs vertical interpolation on a quadruple of floating-point samples.

**interpolateV(float, float, float, float, float)** - Method in class javax.media.jai.InterpolationBilinear  
Performs vertical interpolation on a horizontal quad of floating-point samples.

**interpolateV(int[], int)** - Method in class javax.media.jai.Interpolation  
Performs vertical interpolation on a 1-dimensional array of integral samples.

**interpolateV(int[], int)** - Method in class javax.media.jai.InterpolationTable  
Performs vertical interpolation on a one-dimensional array of integral samples.

**interpolateV(int[], int)** - Method in class javax.media.jai.InterpolationNearest  
Performs vertical interpolation on a one-dimensional array of integral samples.

**interpolateV(int[], int)** - Method in class javax.media.jai.InterpolationBilinear  
Performs vertical interpolation on a one-dimensional array of integral samples.

**interpolateV(int, int, int)** - Method in class javax.media.jai.Interpolation  
Performs vertical interpolation on a pair of integral samples.

**interpolateV(int, int, int)** - Method in class javax.media.jai.InterpolationTable  
Performs vertical interpolation on a pair of integral samples.

**interpolateV(int, int, int)** - Method in class javax.media.jai.InterpolationNearest  
Performs vertical interpolation on a pair of integral samples.

**interpolateV(int, int, int)** - Method in class javax.media.jai.InterpolationBilinear  
Performs vertical interpolation on a pair of integral samples.

**interpolateV(int, int, int, int, int)** - Method in class javax.media.jai.Interpolation  
Performs vertical interpolation on a quadruple of integral samples.

**interpolateV(int, int, int, int, int)** - Method in class javax.media.jai.InterpolationTable  
Performs vertical interpolation on a quadruple of integral samples.

**interpolateV(int, int, int, int, int)** - Method in class javax.media.jai.InterpolationBilinear  
Performs vertical interpolation on a quadruple of integral samples.

**Interpolation** - class javax.media.jai.Interpolation.  
An object encapsulating a particular algorithm for image interpolation (resampling).

**Interpolation()** - Constructor for class javax.media.jai.Interpolation  
Construct Interpolation object with no fields set.

**Interpolation(int, int, int, int, int, int, int)** - Constructor for class javax.media.jai.Interpolation  
Construct interpolation object with all parameters set.

**InterpolationBicubic** - class javax.media.jai.InterpolationBicubic.  
A class representing bicubic interpolation.

**InterpolationBicubic(int)** - Constructor for class javax.media.jai.InterpolationBicubic  
Constructs an InterpolationBicubic with a given subsample precision, in bits.

**InterpolationBicubic2** - class javax.media.jai.InterpolationBicubic2.  
A class representing bicubic interpolation using a different polynomial than InterpolationBicubic.

**InterpolationBicubic2(int)** - Constructor for class javax.media.jai.InterpolationBicubic2  
Constructs an InterpolationBicubic2 with a given subsample precision, in bits.

**InterpolationBilinear** - class javax.media.jai.InterpolationBilinear.  
A class representing bilinear interpolation.

**InterpolationBilinear()** - Constructor for class javax.media.jai.InterpolationBilinear  
Constructs an InterpolationBilinear with the default subsample precision.

**InterpolationBilinear(int)** - Constructor for class javax.media.jai.InterpolationBilinear  
Constructs an InterpolationBilinear with a given subsample precision, in bits.

**InterpolationNearest** - class javax.media.jai.InterpolationNearest.  
A class representing nearest-neighbor interpolation.

**InterpolationNearest()** - Constructor for class javax.media.jai.InterpolationNearest  
Constructs an InterpolationNearest.

**InterpolationTable** - class javax.media.jai.InterpolationTable.  
A subclass of Interpolation that uses tables to store the interpolation kernels.

**InterpolationTable(int, int, int, int, double[])** - Constructor for class javax.media.jai.InterpolationTable  
Constructs an InterpolationTable with identical horizontal and vertical resampling kernels.

**InterpolationTable(int, int, int, int, float[])** - Constructor for class javax.media.jai.InterpolationTable  
Constructs an InterpolationTable with identical horizontal and vertical resampling kernels.

**InterpolationTable(int, int, int, int, int[])** - Constructor for class javax.media.jai.InterpolationTable  
Constructs an InterpolationTable with identical horizontal and vertical resampling kernels.

**InterpolationTable(int, int, int, int, int, int, int, double[], double[])** - Constructor for class javax.media.jai.InterpolationTable  
Constructs an InterpolationTable with specified horizontal and vertical extents (support), number of horizontal and vertical bins, fixed-point fractional precision, and double kernel entries.

**InterpolationTable(int, int, int, int, int, int, int, float[], float[])** - Constructor for class javax.media.jai.InterpolationTable  
Constructs an InterpolationTable with specified horizontal and vertical extents (support), number of horizontal and vertical bins, fixed-point fractional precision, and float kernel entries.

**InterpolationTable(int, int, int, int, int, int, int, int[], int[])** - Constructor for class javax.media.jai.InterpolationTable  
Constructs an InterpolationTable with specified horizontal and vertical extents (support), number of horizontal and vertical bins, fixed-point fractional precision, and int kernel entries.

**intersect(ROI)** - Method in class javax.media.jai.ROI  
Intersects the ROI with another ROI and returns the result as a new ROI.

**intersect(ROI)** - Method in class javax.media.jai.ROIShape  
Sets the mask to its intersection with another mask.

**intersects(double, double, double, double)** - Method in class javax.media.jai.ROI  
Returns true if a given rectangular region intersects the ROI.

**intersects(double, double, double, double)** - Method in class javax.media.jai.ROIShape  
Returns true if a given rectangle (x, y, w, h) intersects the mask.

**intersects(int, int, int, int)** - Method in class javax.media.jai.ROI  
Returns true if a given rectangular region intersects the ROI.

**intersects(int, int, int, int)** - Method in class javax.media.jai.ROIShape  
Returns true if a given rectangle (x, y, w, h) intersects the mask.

**intersects(Rectangle)** - Method in class javax.media.jai.ROI  
Returns true if a given Rectangle intersects the ROI.

**intersects(Rectangle)** - Method in class javax.media.jai.ROIShape  
Returns true if a given Rectangle intersects the mask.

**intersects(Rectangle2D)** - Method in class javax.media.jai.ROI  
Returns true if a given Rectangle2D intersects the ROI.

**intersects(Rectangle2D)** - Method in class javax.media.jai.ROIShape  
Returns true if a given Rectangle2D intersects the mask.

**intersectX(double, int, double, int, int, double[], double[])** - Method in class javax.media.jai.ROIShape.PolyShape  
For the line  $y + 0.5$  calculate the intersection with the segment (x1, y1) to (x2, y2) as well as the slope dx/dy at the point of intersection.

**inverseTransform(double[], int, double[], int, int)** - Method in class javax.media.jai.PerspectiveTransform  
Inverse transforms an array of double precision coordinates by this transform.

**inverseTransform(Point2D, Point2D)** - Method in class javax.media.jai.PerspectiveTransform  
Inverse transforms the specified ptSrc and stores the result in ptDst.

**InvertDescriptor** - class javax.media.jai.operator.InvertDescriptor.  
An OperationDescriptor describing the "Invert" operation.

**InvertDescriptor()** - Constructor for class javax.media.jai.operator.InvertDescriptor  
Constructor.

**invScaleX** - Variable in class javax.media.jai.ScaleOpImage  
Cached value equal to 1/scaleX.

**invScaleXRational** - Variable in class javax.media.jai.ScaleOpImage

**invScaleXRationalDenom** - Variable in class javax.media.jai.ScaleOpImage

**invScaleXRationalNum** - Variable in class javax.media.jai.ScaleOpImage

**invScaleY** - Variable in class javax.media.jai.ScaleOpImage  
Cached value equal to 1/scaleY.

**invScaleYRational** - Variable in class javax.media.jai.ScaleOpImage

**invScaleYRationalDenom** - Variable in class javax.media.jai.ScaleOpImage

**invScaleYRationalNum** - Variable in class javax.media.jai.ScaleOpImage

**isAlphaPremultiplied** - Variable in class javax.media.jai.FloatDoubleColorModel

**isBackgroundSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns true if a 'bKGD' chunk will be output.

**isBackgroundSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Palette  
Returns true if a 'bKGD' chunk will be output.

**isBackgroundSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Gray  
Returns true if a 'bKGD' chunk will be output.

**isBackgroundSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.RGB  
Returns true if a 'bKGD' chunk will be output.

**isBigEndian** - Variable in class com.sun.media.jai.codec.TIFFDirectory  
A boolean storing the endianness of the stream.

**isBigEndian()** - Method in class com.sun.media.jai.codec.TIFFDirectory  
Returns a boolean indicating whether the byte order used in the the TIFF file is big-endian (i.e.

**isBitDepthSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Gray  
Returns true if the bit depth has been set.

**isBitShiftSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Gray  
Returns true if the bit shift has been set.

**isChanged** - Variable in class javax.media.jai.ProductOperationGraph  
Signifies whether the cached copy is out of date.

**isChromaticitySet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns true if a 'cHRM' chunk will be output.

**isCIFChanged** - Variable in class javax.media.jai.OperationGraph

**isCompatibleRaster(Raster)** - Method in class javax.media.jai.FloatDoubleColorModel  
Returns true if the supplied Raster's SampleModel is compatible with this FloatDoubleColorModel.

**isCompatibleSampleModel(SampleModel)** - Method in class javax.media.jai.FloatDoubleColorModel  
Checks whether or not the specified SampleModel is compatible with this ColorModel.

**isCompatibleValue(Object)** - Method in class javax.media.jai.JAI.RenderingKey

**isComplex()** - Method in interface javax.media.jai.ImageFunction  
Returns whether or not each value's elements are complex.

**isCompressed()** - Method in class com.sun.media.jai.codec.BMPEncodeParam  
Returns the value of the parameter compressed.

**isCompressedTextSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns true if a 'zTXT' chunk will be output.

**isDataCopy()** - Method in class javax.media.jai.RasterAccessor  
Returns true if the RasterAccessors's data is copied from it's raster.

**isDynamic()** - Method in class javax.media.jai.RenderableOp  
Returns false, i.e., successive renderings with the same arguments will produce identical results.

**isDynamic()** - Method in class javax.media.jai.RenderableImageAdapter  
Returns true if successive renderings (that is, calls to createRendering() or createScaledRendering()) with the same arguments may produce different results.

**isDynamic()** - Method in class javax.media.jai.MultiResolutionRenderableImage  
Returns false since successive renderings (that is, calls to createRendering() or createScaledRendering()) with the same arguments will never produce different results.

**isDynamic()** - Method in class javax.media.jai.RenderableGraphics

**isEmpty()** - Method in class javax.media.jai.CollectionImage  
Returns true if this collection contains no elements.

**isEmpty()** - Method in class javax.media.jai.CollectionOp  
Returns true if this collection contains no element.

**isFormatRecognized(byte[])** - Method in class com.sun.media.jai.codec.ImageCodec  
Returns true if the format is recognized in the initial portion of a stream.

**isFormatRecognized(SeekableStream)** - Method in class com.sun.media.jai.codec.ImageCodec  
Returns true if the format is recognized in the input data stream.

**isGammaSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns true if a 'gAMA' chunk will be output.

**isHorizontallySymmetric** - Variable in class javax.media.jai.KernelJAI  
True if the kernel has horizontal (Y axis) symmetry.

**isHorizontallySymmetric()** - Method in class javax.media.jai.KernelJAI  
Returns true if the kernel has horizontal (Y axis) symmetry.

**isICCProfileDataSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns true if a 'iCCP' chunk will be output.

**isIdentity()** - Method in class javax.media.jai.PerspectiveTransform  
Returns the boolean true value if this PerspectiveTransform is an identity transform.

**isImmediate()** - Method in interface javax.media.jai.OperationDescriptor  
Returns true if the operation should be rendered immediately during the call to `JAI.create()`; that is, the operation is placed in immediate mode.

**isImmediate()** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns true if the operation should be rendered immediately during the call to `JAI.create()`; that is, the operation is placed in immediate mode.

**isImmediate()** - Method in class javax.media.jai.operator.EncodeDescriptor  
Returns true indicating that the operation should be rendered immediately during a call to `JAI.create()`.

**isImmediate()** - Method in class javax.media.jai.operator.FileStoreDescriptor  
Returns true indicating that the operation should be rendered immediately during a call to `JAI.create()`.

**isInPlaceEnabled** - Variable in class javax.media.jai.PointOpImage

**isIntegralDataType(int)** - Method in class javax.media.jai.LookupTableJAI  
Returns true if the specified data type is an integral data type, such as byte, ushort, short, or int.

**isIntegralDataType(SampleModel)** - Method in class javax.media.jai.LookupTableJAI  
Validates data type.

**isModificationTimeSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns true if a 'tIME' chunk will be output.

**isPaletteHistogramSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns true if a 'hIST' chunk will be output.

**isPaletteSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Palette  
Returns true if a 'PLTE' chunk will be output.

**isPhysicalDimensionSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns true if a 'pHYS' chunk will be output.

**isPixelSequential** - Variable in class javax.media.jai.RasterFormatTag

**isPixelSequential()** - Method in class javax.media.jai.RasterFormatTag  
Returns whether or not the SampleModel represented by the RasterFormatTag is PixelSequential.

**isQTableSet(int)** - Method in class com.sun.media.jai.codec.JPEGEncodeParam  
Tests if a Quantization table has been set.

**isQualitySet()** - Method in class com.sun.media.jai.codec.JPEGEncodeParam  
Tests if the quality parameter has been set in this JPEGEncodeParam.

**isRenderableSupported()** - Method in interface javax.media.jai.OperationDescriptor  
Returns true if this operation supports the renderable image mode.

**isRenderableSupported()** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns true if this operation supports the renderable mode.

**isRenderableSupported()** - Method in class javax.media.jai.operator.RenderableDescriptor  
Indicates that renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.DCTDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.PolarToComplexDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.LookupDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.IDCTDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.MultiplyDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.MagnitudeDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.XorConstDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.CompositeDescriptor  
Returns true since renderable operation is supported.

[illegible]

**isRenderableSupported()** - Method in class javax.media.jai.operator.PiecewiseDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.IDFTDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.IIPDescriptor  
Overrides super class's default implementation to return true because this operation supports renderable mode.

**isRenderableSupported()** - Method in class javax.media.jai.operator.MagnitudeSquaredDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.MinDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.ConjugateDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.DivideIntoConstDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.DivideComplexDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.InvertDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.XorDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.ScaleDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.ColorConvertDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.DivideDescriptor  
Returns true since renderable operation is supported.

**isRenderableSupported()** - Method in class javax.media.jai.operator.OrDescriptor  
Returns true since renderable operation is supported.

**isRendered** - Variable in class javax.media.jai.PropertySourceImpl

**isRenderedSupported()** - Method in interface javax.media.jai.OperationDescriptor  
Returns true if this operation supports the rendered image mode.

**isRenderedSupported()** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns true if this operation supports the rendered mode.

**isRenderedSupported()** - Method in class javax.media.jai.operator.RenderableDescriptor  
Indicates that rendered operation is supported.

**isRIFChanged** - Variable in class javax.media.jai.OperationGraph

**isSeparable** - Variable in class javax.media.jai.KernelJAI  
True if the kernel is separable.

**isSeparable()** - Method in class javax.media.jai.Interpolation  
Returns true if the interpolation can be performed in a separable manner, that is, by performing a separate pass in each dimension.

**isSeparable()** - Method in class javax.media.jai.KernelJAI  
Returns true if the kernel is separable.

**isSignificantBitsSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns true if an 'sBIT' chunk will be output.

**isSorted** - Variable in class javax.media.jai.IntegerSequence  
True if iArray has been sorted and purged of duplicates.

**isSRGBIntentSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns true if an 'sRGB' chunk will be output.

**isSuggestedPaletteSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns true if a 'sPLT' chunk will be output.

**isTagPresent(int)** - Method in class com.sun.media.jai.codec.TIFFDirectory  
Returns true if a tag appears in the directory.

**isTextSet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns true if a 'tEXt' chunk will be output.

**isTileLocked(int, int)** - Method in class javax.media.jai.TiledImage  
Returns true if a tile is locked.

**isTileWritable(int, int)** - Method in class javax.media.jai.WritableRenderedImageAdapter  
Return whether a tile is currently checked out for writing.

**isTileWritable(int, int)** - Method in class javax.media.jai.TiledImage  
Returns true if a tile has writers.

**isTopDown()** - Method in class com.sun.media.jai.codec.BMPEncodeParam  
Returns the value of the topDown parameter.

**isTransparencySet()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Returns true if a 'tRNS' chunk will be output.

**isValid(int)** - Method in class javax.media.jai.ImageLayout  
Returns true if all the parameters specified by the argument are set.

**isValidColorMap(RenderedImage, ColorCube, StringBuffer)** - Static method in class javax.media.jai.operator.OrderedDitherDescriptor  
Method to check the validity of the color map parameter.

**isValidDitherMask(RenderedImage, KernelJAI[], StringBuffer)** - Static method in class javax.media.jai.operator.OrderedDitherDescriptor  
Method to check the validity of the dither mask parameter.

**isValidEndianTag(int)** - Static method in class com.sun.media.jai.codec.TIFFDirectory

**isVerticallySymmetric** - Variable in class javax.media.jai.KernelJAI  
True if the kernel has vertical (X axis) symmetry.

**isVerticallySymmetric()** - Method in class javax.media.jai.KernelJAI  
Returns true if the kernel has vertical (X axis) symmetry.

**iter** - Variable in class javax.media.jai.ROI  
A RandomIter used to grab pixels from the ROI.

**iterator()** - Method in class javax.media.jai.CollectionImage  
Returns an Iterator over the elements in this collection.

**iterator()** - Method in class javax.media.jai.CollectionOp  
Returns an iterator over the elements in this collection.

---

## J

**JAI** - class javax.media.jai.JAI.  
A convenience class for instantiating operations.

**JAI.RenderingKey** - class javax.media.jai.JAI.RenderingKey.  
Rendering hints.

**JAI.RenderingKey(int, Class)** - Constructor for class javax.media.jai.JAI.RenderingKey

**JAI()** - Constructor for class javax.media.jai.JAI  
Returns a new instance of the JAI class.

**JAI(OperationRegistry, TileScheduler, TileCache, RenderingHints)** - Constructor for class javax.media.jai.JAI  
Returns a new instance of the JAI class.

**JaiI18N** - class javax.media.jai.JaiI18N.

**JaiI18N** - class javax.media.jai.iterator.JaiI18N.

**JaiI18N** - class javax.media.jai.operator.JaiI18N.

**JaiI18N** - class javax.media.jai.widget.JaiI18N.

**JaiI18N** - class com.sun.media.jai.codec.JaiI18N.

**JaiI18N()** - Constructor for class javax.media.jai.JaiI18N

**JaiI18N()** - Constructor for class javax.media.jai.iterator.JaiI18N

**JaiI18N()** - Constructor for class javax.media.jai.operator.JaiI18N

**JaiI18N()** - Constructor for class javax.media.jai.widget.JaiI18N

**JaiI18N()** - Constructor for class com.sun.media.jai.codec.JaiI18N

**JAIorderBands(int[], int)** - Method in class javax.media.jai.ComponentSampleModelJAI  
Preserves band ordering with new step factor...

javax.media.jai - package javax.media.jai

javax.media.jai.iterator - package javax.media.jai.iterator

javax.media.jai.operator - package javax.media.jai.operator

javax.media.jai.widget - package javax.media.jai.widget

**JPEG\_MAX\_BANDS** - Static variable in class com.sun.media.jai.codec.JPEGEncodeParam

**JPEGDescriptor** - class javax.media.jai.operator.JPEGDescriptor.  
 An `OperationDescriptor` describing the "JPEG" operation.

**JPEGDescriptor()** - Constructor for class javax.media.jai.operator.JPEGDescriptor  
 Constructor.

**JPEGEncodeParam** - class com.sun.media.jai.codec.JPEGEncodeParam.  
 A class which encapsulates the most common functionality required for the parameters to a Jpeg encode operation.

**JPEGEncodeParam()** - Constructor for class com.sun.media.jai.codec.JPEGEncodeParam  
 Constructs a JAI `JPEGEncodeParam` object with default settings.

**jumpLines(int)** - Method in interface javax.media.jai.iterator.RectIter  
 Jumps downward num lines from the current position.

**jumpPixels(int)** - Method in interface javax.media.jai.iterator.RectIter  
 Jumps rightward num pixels from the current position.

---

## K

**KernelJAI** - class javax.media.jai.KernelJAI.  
 A kernel, used by the Convolve, Ordered Dither, and Error Diffusion operations.

**KernelJAI(int, int, float[])** - Constructor for class javax.media.jai.KernelJAI  
 Constructs a kernel with the given parameters.

**KernelJAI(int, int, int, int, float[])** - Constructor for class javax.media.jai.KernelJAI  
 Constructs a `KernelJAI` with the given parameters.

**KernelJAI(int, int, int, int, float[], float[])** - Constructor for class javax.media.jai.KernelJAI  
 Constructs a separable `KernelJAI` from two float arrays.

**KernelJAI(Kernel)** - Constructor for class javax.media.jai.KernelJAI  
 Constructs a `KernelJAI` from a java.awt.image.Kernel object.

**KEY\_BORDER\_EXTENDER** - Static variable in class javax.media.jai.JAI  
 Key for `BorderExtender` object values.

**KEY\_IMAGE\_LAYOUT** - Static variable in class javax.media.jai.JAI  
 Key for `ImageLayout` object values.

**KEY\_INTERPOLATION** - Static variable in class javax.media.jai.JAI  
 Key for `Interpolation` object values.

**KEY\_OPERATION\_BOUND** - Static variable in class javax.media.jai.JAI  
 Key for `Integer` object values representing whether the operation is compute, network, or I/O bound.

**KEY\_OPERATION\_REGISTRY** - Static variable in class javax.media.jai.JAI  
 Key for `OperationRegistry` object values.

**KEY\_TILE\_CACHE** - Static variable in class javax.media.jai.JAI  
 Key for `TileCache` object values.

---

## L

**lastSegmentLength** - Variable in class com.sun.media.jai.codec.SectorStreamSegmentMapper

**layoutHelper(ImageLayout, RenderedImage)** - Static method in class javax.media.jai.UntiledOpImage  
 Creates the `ImageLayout` for the image.

**layoutHelper(int, int, int, int, SampleModel, ImageLayout)** - Static method in class javax.media.jai.SourcelessOpImage

**layoutHelper(RenderedImage)** - Static method in class javax.media.jai.StatisticsOpImage

**layoutHelper(RenderedImage, float, float, float, float, ImageLayout)** - Static method in class javax.media.jai.ScaleOpImage

**layoutHelper(RenderedImage, ImageLayout)** - Static method in class javax.media.jai.NullOpImage

**leftPadding** - Variable in class javax.media.jai.Interpolation  
 The number of pixels lying to the left of the interpolation kernel key position.

**leftPadding** - Variable in class javax.media.jai.AreaOpImage  
 The number of source pixels needed to the left of the central pixel.

**length** - Variable in class com.sun.media.jai.codec.ByteArraySeekableStream  
 The length of the valid segment of the array.

**length** - Variable in class com.sun.media.jai.codec.MemoryCacheSeekableStream  
 Number of bytes read.

**length** - Variable in class com.sun.media.jai.codec.FileCacheSeekableStream  
 Number of bytes in the cache.

**length** - Variable in class com.sun.media.jai.codec.FileSeekableStream

**length()** - Method in class com.sun.media.jai.codec.ByteArraySeekableStream  
Returns the number of valid bytes in the input array.

**loadDescriptors(RegistryInitData)** - Method in class javax.media.jai.OperationRegistry  
A method for registry initialization.

**localProperties** - Variable in class javax.media.jai.RenderedOp  
Locally-stored properties.

**localProperties** - Variable in class javax.media.jai.RenderableOp  
Locally-stored properties.

**lock** - Variable in class javax.media.jai.OperationGraph

**lock** - Variable in class javax.media.jai.ProductOperationGraph

**lock** - Variable in class javax.media.jai.OperationRegistry  
The ReaderWriter Lock for this class.

**lockTile(int, int)** - Method in class javax.media.jai.TiledImage  
Forces a tile to be computed, and its contents stored indefinitely.

**LogDescriptor** - class javax.media.jai.operator.LogDescriptor.  
An OperationDescriptor describing the "Log" operation.

**LogDescriptor()** - Constructor for class javax.media.jai.operator.LogDescriptor  
Constructor.

**lookup(int, int)** - Method in class javax.media.jai.LookupTableJAI  
Performs lookup on a given value belonging to a given source band, and returns the result as an int.

**lookup(int, int, int[], byte[][], int, int, int, int, int[], byte[][], int[], byte[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], byte[][], int, int, int, int, int, int[], double[][], int[], double[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], byte[][], int, int, int, int, int, int[], float[][], int[], float[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], byte[][], int, int, int, int, int, int[], int[][], int[], int[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], byte[][], int, int, int, int, int, int[], short[][], int[], short[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], int[][], int, int, int, int, int, int[], byte[][], int[], byte[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], int[][], int, int, int, int, int, int[], double[][], int[], double[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], int[][], int, int, int, int, int, int[], float[][], int[], float[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], int[][], int, int, int, int, int, int[], int[][], int[], int[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], int[][], int, int, int, int, int, int[], short[][], int[], short[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], short[][], int, int, int, int, int, int[], byte[][], int[], byte[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], short[][], int, int, int, int, int, int[], double[][], int[], double[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], short[][], int, int, int, int, int, int[], float[][], int[], float[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], short[][], int, int, int, int, int, int[], int[][], int[], int[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(int, int, int[], short[][], int, int, int, int, int, int[], short[][], int[], short[][])** - Method in class javax.media.jai.LookupTableJAI

**lookup(Raster, WritableRaster, Rectangle)** - Method in class javax.media.jai.LookupTableJAI  
 Performs table lookup on a source Raster, writing the result into a supplied WritableRaster.

**lookup(WritableRaster)** - Method in class javax.media.jai.LookupTableJAI  
 Performs table lookup in place on a given WritableRaster.

**lookupCIF(CollectionImageFactory)** - Method in class javax.media.jai.OperationGraph  
 Locates a CIF within the vector of PartialOrderNodes.

**LookupDescriptor** - class javax.media.jai.operator.LookupDescriptor.  
 An OperationDescriptor describing the "Lookup" operation.

**LookupDescriptor()** - Constructor for class javax.media.jai.operator.LookupDescriptor  
 Constructor.

**lookupDouble(int, int)** - Method in class javax.media.jai.LookupTableJAI  
 Performs lookup on a given value belonging to a given source band, and returns the result as a double.

**lookupFloat(int, int)** - Method in class javax.media.jai.LookupTableJAI  
 Performs lookup on a given value belonging to a given source band, and returns the result as a float.

**lookupOp(String)** - Method in class javax.media.jai.ProductOperationGraph  
 Locates a product from within the vector of PartialOrderNodes using the productName provided.

**lookupRIF(RenderedImageFactory)** - Method in class javax.media.jai.OperationGraph  
 Locates a RIF within the vector of PartialOrderNodes.

**LookupTableJAI** - class javax.media.jai.LookupTableJAI.  
 A lookup table object associated with the "Lookup" operation.

**LookupTableJAI(byte[])** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a single-banded byte lookup table.

**LookupTableJAI(byte[][])** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded byte lookup table.

**LookupTableJAI(byte[][], int)** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded byte lookup table where all bands have the same index offset.

**LookupTableJAI(byte[][], int[])** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded byte lookup table where each band has a different index offset.

**LookupTableJAI(byte[], int)** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a single-banded byte lookup table with an index offset.

**LookupTableJAI(double[])** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a single-banded double lookup table.

**LookupTableJAI(double[][])** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded double lookup table.

**LookupTableJAI(double[][], int)** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded double lookup table where all bands have the same index offset.

**LookupTableJAI(double[][], int[])** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded double lookup table where each band has a different index offset.

**LookupTableJAI(double[], int)** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a single-banded double lookup table with an index offset.

**LookupTableJAI(float[])** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a single-banded float lookup table.

**LookupTableJAI(float[][])** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded float lookup table.

**LookupTableJAI(float[][], int)** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded float lookup table where all bands have the same index offset.

**LookupTableJAI(float[][], int[])** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded float lookup table where each band has a different index offset.

**LookupTableJAI(float[], int)** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a single-banded float lookup table with an index offset.

**LookupTableJAI(int[])** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a single-banded int lookup table.

**LookupTableJAI(int[][])** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded int lookup table.

**LookupTableJAI(int[][], int)** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded int lookup table where all bands have the same index offset.

**LookupTableJAI(int[][], int[])** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded int lookup table where each band has a different index offset.

**LookupTableJAI(int[], int)** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a single-banded int lookup table with an index offset.

**LookupTableJAI(short[][], boolean)** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded short or unsigned short lookup table.

**LookupTableJAI(short[][], int[], boolean)** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded short or unsigned short lookup table where each band has a different index offset.

**LookupTableJAI(short[][], int, boolean)** - Constructor for class javax.media.jai.LookupTableJAI  
 Constructs a multi-banded short or unsigned short lookup table where all bands have the same index offset.

**LookupTableJAI(short[], boolean)** - Constructor for class javax.media.jai.LookupTableJAI  
Constructs a single-banded short or unsigned short lookup table.

**LookupTableJAI(short[], int, boolean)** - Constructor for class javax.media.jai.LookupTableJAI  
Constructs a single-banded short or unsigned short lookup table with an index offset.

**lookupU(int, int, int[], short[], int, int, int, int, int, int[], byte[], int[], byte[])** - Method in class javax.media.jai.LookupTableJAI

**lookupU(int, int, int[], short[], int, int, int, int, int, int[], double[], int[], double[])** - Method in class javax.media.jai.LookupTableJAI

**lookupU(int, int, int[], short[], int, int, int, int, int, int[], float[], int[], float[])** - Method in class javax.media.jai.LookupTableJAI

**lookupU(int, int, int[], short[], int, int, int, int, int, int[], int[], int[], int[])** - Method in class javax.media.jai.LookupTableJAI

**lookupU(int, int, int[], short[], int, int, int, int, int, int[], short[], int[], short[])** - Method in class javax.media.jai.LookupTableJAI

**lowValue** - Variable in class javax.media.jai.Histogram  
The lowest pixel value of the image checked for each band.

**lpad** - Variable in class javax.media.jai.ScaleOpImage

---

## M

**m00** - Variable in class javax.media.jai.PerspectiveTransform  
An element of the transform matrix.

**m01** - Variable in class javax.media.jai.PerspectiveTransform  
An element of the transform matrix.

**m02** - Variable in class javax.media.jai.PerspectiveTransform  
An element of the transform matrix.

**m10** - Variable in class javax.media.jai.PerspectiveTransform  
An element of the transform matrix.

**m11** - Variable in class javax.media.jai.PerspectiveTransform  
An element of the transform matrix.

**m12** - Variable in class javax.media.jai.PerspectiveTransform  
An element of the transform matrix.

**m20** - Variable in class javax.media.jai.PerspectiveTransform  
An element of the transform matrix.

**m21** - Variable in class javax.media.jai.PerspectiveTransform  
An element of the transform matrix.

**m22** - Variable in class javax.media.jai.PerspectiveTransform  
An element of the transform matrix.

**MagnitudeDescriptor** - class javax.media.jai.operator.MagnitudeDescriptor.  
An `OperationDescriptor` describing the "Magnitude" operation.

**MagnitudeDescriptor()** - Constructor for class javax.media.jai.operator.MagnitudeDescriptor  
Constructor.

**MagnitudePropertyGenerator** - class javax.media.jai.operator.MagnitudePropertyGenerator.  
This property generator computes the properties for the operation "Magnitude" dynamically.

**MagnitudePropertyGenerator()** - Constructor for class javax.media.jai.operator.MagnitudePropertyGenerator  
Constructor.

**MagnitudeSquaredDescriptor** - class javax.media.jai.operator.MagnitudeSquaredDescriptor.  
An `OperationDescriptor` describing the "MagnitudeSquared" operation.

**MagnitudeSquaredDescriptor()** - Constructor for class javax.media.jai.operator.MagnitudeSquaredDescriptor  
Constructor.

**MagnitudeSquaredPropertyGenerator** - class javax.media.jai.operator.MagnitudeSquaredPropertyGenerator.  
This property generator computes the properties for the operation "MagnitudeSquared" dynamically.

**MagnitudeSquaredPropertyGenerator()** - Constructor for class javax.media.jai.operator.MagnitudeSquaredPropertyGenerator  
Constructor.

**makeAdjoint()** - Method in class javax.media.jai.PerspectiveTransform  
Replaces the matrix with its adjoint.

**mapDestPoint(int, int)** - Method in class javax.media.jai.WarpAffine

**mapDestRect(Rectangle)** - Method in class javax.media.jai.Warp  
Computes a rectangle that is guaranteed to enclose the region of the source that is required in order to produce a given rectangular output region.

**mapDestRect(Rectangle)** - Method in class javax.media.jai.WarpPolynomial  
Computes a Rectangle that is guaranteed to enclose the region of the source that is required in order to produce a given rectangular output region.

**mapDestRect(Rectangle)** - Method in class javax.media.jai.WarpAffine  
Computes a Rectangle that is guaranteed to enclose the region of the source that is required in order to produce a given rectangular output region.

**mapDestRect(Rectangle)** - Method in class javax.media.jai.WarpPerspective  
Computes a Rectangle that is guaranteed to enclose the region of the source that is required in order to produce a given rectangular output region.

**mapDestRect(Rectangle)** - Method in class javax.media.jai.WarpGrid  
Computes a Rectangle that is guaranteed to enclose the region of the source that is required in order to produce a given rectangular output region.

**mapDestRect(Rectangle, int)** - Method in class javax.media.jai.OpImage  
Returns a conservative estimate of the region of a specified source that is required in order to compute the pixels of a given destination rectangle.

**mapDestRect(Rectangle, int)** - Method in class javax.media.jai.SourcelessOpImage  
Throws an IllegalArgumentException since the image has no image sources.

**mapDestRect(Rectangle, int)** - Method in class javax.media.jai.PointOpImage  
Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**mapDestRect(Rectangle, int)** - Method in class javax.media.jai.WarpOpImage  
Returns a conservative estimate of the region of a specified source that is required in order to compute the pixels of a given destination rectangle.

**mapDestRect(Rectangle, int)** - Method in class javax.media.jai.ScaleOpImage  
Returns a conservative estimate of the region of a specified source that is required in order to compute the pixels of a given destination rectangle.

**mapDestRect(Rectangle, int)** - Method in class javax.media.jai.AreaOpImage  
Returns a conservative estimate of the region of a specified source that is required in order to compute the pixels of a given destination rectangle.

**mapDestRect(Rectangle, int)** - Method in class javax.media.jai.StatisticsOpImage  
Maps the destination rectangle into source space unchanged.

**mapDestRect(Rectangle, int)** - Method in class javax.media.jai.UntiledOpImage  
Returns a conservative estimate of the region of a specified source that is required in order to compute the pixels of a given destination rectangle.

**mapper** - Variable in class com.sun.media.jai.codec.SegmentedSeekableStream

**mapSourceRect(Rectangle)** - Method in class javax.media.jai.Warp  
Computes a rectangle that is guaranteed to enclose the region of the destination that can potentially be affected by the pixels of a rectangle of a given source.

**mapSourceRect(Rectangle, int)** - Method in class javax.media.jai.OpImage  
Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**mapSourceRect(Rectangle, int)** - Method in class javax.media.jai.SourcelessOpImage  
Throws an IllegalArgumentException since the image has no image sources.

**mapSourceRect(Rectangle, int)** - Method in class javax.media.jai.PointOpImage  
Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**mapSourceRect(Rectangle, int)** - Method in class javax.media.jai.WarpOpImage  
Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**mapSourceRect(Rectangle, int)** - Method in class javax.media.jai.ScaleOpImage  
Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**mapSourceRect(Rectangle, int)** - Method in class javax.media.jai.AreaOpImage  
Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**mapSourceRect(Rectangle, int)** - Method in class javax.media.jai.StatisticsOpImage  
Maps the source rectangle into destination space unchanged.

**mapSourceRect(Rectangle, int)** - Method in class javax.media.jai.UntiledOpImage  
Returns a conservative estimate of the destination region that can potentially be affected by the pixels of a rectangle of a given source.

**mark(int)** - Method in class com.sun.media.jai.codec.SeekableStream  
Marks the current file position for later return using the `reset()` method.

**mark(int)** - Method in class com.sun.media.jai.codec.ForwardSeekableStream  
Forwards the request to the real `InputStream`.

**mark(int)** - Method in class com.sun.media.jai.codec.FileSeekableStream  
Marks the current file position for later return using the `reset()` method.

**markPos** - Variable in class com.sun.media.jai.codec.SeekableStream  
Marked position

**markPos** - Variable in class com.sun.media.jai.codec.ForwardSeekableStream  
The marked position.

**markPos** - Variable in class com.sun.media.jai.codec.FileSeekableStream

**markSupported()** - Method in class com.sun.media.jai.codec.SeekableStream  
Returns `true` if marking is supported.

**markSupported()** - Method in class com.sun.media.jai.codec.ForwardSeekableStream  
Forwards the request to the real `InputStream`.

**markSupported()** - Method in class com.sun.media.jai.codec.FileSeekableStream  
Returns `true` since marking is supported.

**MatchCDFDescriptor** - class javax.media.jai.operator.MatchCDFDescriptor.  
An `OperationDescriptor` describing the "MatchCDF" operation.

**MatchCDFDescriptor()** - Constructor for class javax.media.jai.operator.MatchCDFDescriptor  
Constructor.

**max** - Variable in class javax.media.jai.IntegerSequence  
Upper bound of the valid integer range.

**MAX\_RESOLUTION** - Static variable in class javax.media.jai.operator.IIPResolutionDescriptor  
Convenience name for Max Resolution of an image on an IIP server.

**MAX\_RESOLUTION** - Static variable in class javax.media.jai.operator.FPXDescriptor  
Convenience name for the Max Resolution of an FPX image

**MaxDescriptor** - class javax.media.jai.operator.MaxDescriptor.  
An `OperationDescriptor` describing the "Max" operation.

**MaxDescriptor()** - Constructor for class javax.media.jai.operator.MaxDescriptor  
Constructor.

**maxHeight** - Variable in class javax.media.jai.StatisticsOpImage  
The largest allowable height of the source argument to accumulateStatistics.

**maxTileX** - Variable in class javax.media.jai.widget.ImageCanvas  
The image's max X tile.

**maxTileY** - Variable in class javax.media.jai.widget.ImageCanvas  
The image's max Y tile.

**maxWidth** - Variable in class javax.media.jai.StatisticsOpImage  
The largest allowable width of the source argument to accumulateStatistics.

**MeanDescriptor** - class javax.media.jai.operator.MeanDescriptor.  
An `OperationDescriptor` describing the "Mean" operation.

**MeanDescriptor()** - Constructor for class javax.media.jai.operator.MeanDescriptor  
Constructor.

**MEDIAN\_MASK\_PLUS** - Static variable in class javax.media.jai.operator.MedianFilterDescriptor  
Plus shaped mask.

**MEDIAN\_MASK\_SQUARE** - Static variable in class javax.media.jai.operator.MedianFilterDescriptor  
Square shaped mask.

**MEDIAN\_MASK\_SQUARE\_SEPARABLE** - Static variable in class javax.media.jai.operator.MedianFilterDescriptor  
Separable square mask.

**MEDIAN\_MASK\_X** - Static variable in class javax.media.jai.operator.MedianFilterDescriptor  
X shaped mask.

**MedianFilterDescriptor** - class javax.media.jai.operator.MedianFilterDescriptor.  
An `OperationDescriptor` describing the "MedianFilter" operation.

**MedianFilterDescriptor()** - Constructor for class javax.media.jai.operator.MedianFilterDescriptor  
Constructor for the MedianFilterDescriptor.

**MemoryCacheSeekableStream** - class com.sun.media.jai.codec.MemoryCacheSeekableStream.  
A subclass of `SeekableStream` that may be used to wrap a regular `InputStream`.

**MemoryCacheSeekableStream(InputStream)** - Constructor for class com.sun.media.jai.codec.MemoryCacheSeekableStream  
Constructs a `MemoryCacheSeekableStream` that takes its source data from a regular `InputStream`.

**mergeImages(PlanarImage, PlanarImage, PlanarImage)** - Static method in class javax.media.jai.ROI

**mergeRunLengthList(LinkedList)** - Static method in class javax.media.jai.ROI  
Merge a `LinkedList` of `Rectangles` representing run lengths of pixels in the ROI into a minimal list wherein vertically abutting `Rectangles` are merged.

**mergeTypes(int, int)** - Static method in class javax.media.jai.OpImage  
Returns a type (one of the enumerated constants from `DataBuffer`) that has sufficient range to contain values from either of two given types.

**min** - Variable in class javax.media.jai.IntegerSequence  
Lower bound of the valid integer range.

**MIN\_ARRAYCOPY\_SIZE** - Static variable in class javax.media.jai.PlanarImage

**MIN\_X\_MASK** - Static variable in class javax.media.jai.ImageLayout  
A bitmask to specify the validity of minX.

**MIN\_Y\_MASK** - Static variable in class javax.media.jai.ImageLayout  
A bitmask to specify the validity of minY.

**MinDescriptor** - class javax.media.jai.operator.MinDescriptor.  
An OperationDescriptor describing the "Min" operation.

**MinDescriptor()** - Constructor for class javax.media.jai.operator.MinDescriptor  
Constructor.

**minTileX** - Variable in class javax.media.jai.TiledImage  
The index of the leftmost column of tiles.

**minTileX** - Variable in class javax.media.jai.widget.ImageCanvas  
The image's min X tile.

**minTileY** - Variable in class javax.media.jai.TiledImage  
The index of the uppermost row of tiles.

**minTileY** - Variable in class javax.media.jai.widget.ImageCanvas  
The image's min Y tile.

**minX** - Variable in class javax.media.jai.ImageLayout  
The image's minimum X coordinate.

**minX** - Variable in class javax.media.jai.PlanarImage  
The X coordinate of the image's upper-left pixel.

**minX** - Variable in class javax.media.jai.MultiResolutionRenderableImage  
The min X coordinate in Renderable coordinates.

**minY** - Variable in class javax.media.jai.ImageLayout  
The image's minimum Y coordinate.

**minY** - Variable in class javax.media.jai.PlanarImage  
The Y coordinate of the image's upper-left pixel.

**minY** - Variable in class javax.media.jai.MultiResolutionRenderableImage  
The min Y coordinate in Renderable coordinates.

**modificationTime** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**modificationTimeSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**mouseClicked(MouseEvent)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Ignored.

**mouseDragged(MouseEvent)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Called by the AWT as the mouse is dragged.

**mouseEntered(MouseEvent)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Ignored.

**mouseExited(MouseEvent)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Called by the AWT when the mouse leaves the component.

**mouseMoved(MouseEvent)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Ignored.

**mousePressed(MouseEvent)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Called by the AWT when the mouse button is pressed.

**mouseReleased(MouseEvent)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Called by the AWT when the mouse button is released.

**moveSource** - Variable in class javax.media.jai.widget.ScrollingImagePanel  
The initial Point of a mouse drag.

**multipliers** - Variable in class javax.media.jai.ColorCube  
An array of multipliers.

**MultiplyComplexDescriptor** - class javax.media.jai.operator.MultiplyComplexDescriptor.  
An OperationDescriptor describing the "MultiplyComplex" operation.

**MultiplyComplexDescriptor()** - Constructor for class javax.media.jai.operator.MultiplyComplexDescriptor  
Constructor.

**MultiplyComplexPropertyGenerator** - class javax.media.jai.operator.MultiplyComplexPropertyGenerator.  
This property generator computes the properties for the operation "MultiplyComplex" dynamically.

**MultiplyComplexPropertyGenerator()** - Constructor for class javax.media.jai.operator.MultiplyComplexPropertyGenerator  
Constructor.

**MultiplyConstDescriptor** - class javax.media.jai.operator.MultiplyConstDescriptor.  
An OperationDescriptor describing the "MultiplyConst" operation.

**MultiplyConstDescriptor()** - Constructor for class javax.media.jai.operator.MultiplyConstDescriptor  
Constructor.

**MultiplyDescriptor** - class javax.media.jai.operator.MultiplyDescriptor.  
 An `OperationDescriptor` describing the "Multiply" operation.  
**MultiplyDescriptor()** - Constructor for class javax.media.jai.operator.MultiplyDescriptor  
 Constructor.  
**MultiResolutionRenderableImage** - class javax.media.jai.MultiResolutionRenderableImage.  
 A `RenderableImage` that produces renderings based on a set of supplied `RenderedImages` at various resolutions.  
**MultiResolutionRenderableImage(Vector, float, float, float)** - Constructor for class  
 javax.media.jai.MultiResolutionRenderableImage  
 Constructs a `MultiResolutionRenderableImage` with given dimensions from a `Vector` of progressively lower resolution  
 versions of a `RenderedImage`.

---

## N

**name** - Variable in class javax.media.jai.OperationDescriptorImpl  
 The global name of this operation.  
**name** - Variable in class javax.media.jai.PartialOrderNode  
 The name of the object associated with this node.  
**name** - Variable in class javax.media.jai.Storage  
 The name of the entry.  
**name** - Variable in class com.sun.media.jai.codec.PNGSuggestedPaletteEntry  
 The name of the entry.  
**nearestInstance** - Static variable in class javax.media.jai.Interpolation  
 The nearest instance.  
**needsClamping()** - Method in class javax.media.jai.RasterAccessor  
 Indicates if the `RasterAccessor` has a larger dynamic range than the underlying `Raster`.  
**neighbors** - Variable in class javax.media.jai.PartialOrderNode  
 A `Vector` of neighboring nodes.  
**next** - Variable in class javax.media.jai.Snapshot  
 The next `Snapshot` in a doubly-linked list.  
**nextBand()** - Method in interface javax.media.jai.iterator.RectIter  
 Sets the iterator to the next band in the image.  
**nextBandDone()** - Method in interface javax.media.jai.iterator.RectIter  
 Sets the iterator to the next band in the image, and returns true if the max band has been exceeded.  
**nextElement()** - Method in class javax.media.jai.IntegerSequence  
 Returns the next element of the iteration in ascending order.  
**nextLine()** - Method in interface javax.media.jai.iterator.RectIter  
 Sets the iterator to the next line of the image.  
**nextLineDone()** - Method in interface javax.media.jai.iterator.RectIter  
 Sets the iterator to the next line in the image, and returns true if the bottom row of the bounding rectangle has been  
 passed.  
**nextPixel()** - Method in interface javax.media.jai.iterator.RectIter  
 Sets the iterator to the next pixel in image (that is, move rightward).  
**nextPixelDone()** - Method in interface javax.media.jai.iterator.RectIter  
 Sets the iterator to the next pixel in the image (that is, move rightward).  
**NO\_DESTINATION\_ALPHA** - Static variable in class javax.media.jai.operator.CompositeDescriptor  
 The destination image does not have the alpha channel.  
**NO\_PARAMETER\_DEFAULT** - Static variable in interface javax.media.jai.OperationDescriptor  
 An `Object` that signifies that a parameter has no default value.  
**nodeData** - Variable in class javax.media.jai.PartialOrderNode  
 The data associated with this node.  
**NoParameterDefault** - class javax.media.jai.NoParameterDefault.  
 A class that signifies that a parameter has no default value.  
**NoParameterDefault()** - Constructor for class javax.media.jai.NoParameterDefault  
 Constructor.  
**normalize()** - Method in class javax.media.jai.PerspectiveTransform  
 Scales the matrix elements so m22 is equal to 1.0.  
**NotDescriptor** - class javax.media.jai.operator.NotDescriptor.  
 An `OperationDescriptor` describing the "Not" operation.  
**NotDescriptor()** - Constructor for class javax.media.jai.operator.NotDescriptor  
 Constructor.  
**notifyViewportListeners(int, int, int, int)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
 Notifies the viewport listeners.  
**noWarpSparseRect(int, int, int, int, int, int, int, int, float[])** - Method in class javax.media.jai.WarpGrid  
 Copies source to destination, no warpping.  
**NULL\_PROPERTY\_CLASS** - Static variable in class javax.media.jai.RemoteImage  
 The null property class.

**NullOpImage** - class javax.media.jai.NullOpImage.  
 A trivial OpImage subclass that simply transmits its source unchanged.

**NullOpImage(RenderedImage, TileCache, int, ImageLayout)** - Constructor for class javax.media.jai.NullOpImage  
 Constructs a NullOpImage.

**NUM\_PAGES** - Static variable in class com.sun.media.jai.codec.FileSeekableStream

**NUM\_VARS** - Static variable in class javax.media.jai.RemoteImage  
 Index of local variable.

**numBands** - Variable in class javax.media.jai.RasterFormatTag

**numBands** - Variable in class javax.media.jai.ColorCube  
 The number of bands cached to accelerate findNearestEntry().

**numBands** - Variable in class javax.media.jai.Histogram  
 The number of bands in the image which the histogram is taken.

**numBands** - Variable in class javax.media.jai.RasterAccessor  
 The number of bands per pixel in the data array.

**numBins** - Variable in class javax.media.jai.Histogram  
 The number of bins used for each band of the image.

**numColorComponents** - Variable in class javax.media.jai.FloatDoubleColorModel

**numComponents** - Variable in class javax.media.jai.FloatDoubleColorModel

**numElts** - Variable in class javax.media.jai.IntegerSequence  
 The number of (non-unique) elements actually stored in iArray.

**numEntries** - Variable in class com.sun.media.jai.codec.TIFFDirectory  
 The number of entries in the IFD.

**numRetries** - Variable in class javax.media.jai.RemoteImage  
 The number of retries.

**numSources** - Variable in class javax.media.jai.MultiResolutionRenderableImage

**numSubsamplesH** - Variable in class javax.media.jai.InterpolationTable  
 The number of horizontal subpixel positions within a pixel.

**numSubsamplesV** - Variable in class javax.media.jai.InterpolationTable  
 The number of vertical subpixel positions within a pixel.

**numWritableTiles** - Variable in class javax.media.jai.TiledImage

## O

**object1** - Variable in class javax.media.jai.Store

**object2** - Variable in class javax.media.jai.Store

**objectClass** - Variable in class javax.media.jai.JAI.RenderingKey

**odesc** - Variable in class javax.media.jai.ParameterBlockJAI  
 The OperationDescriptor associated with this ParameterBlockJAI.

**offset** - Variable in class com.sun.media.jai.codec.ByteArraySeekableStream  
 The starting offset within the array.

**one** - Variable in class javax.media.jai.InterpolationBilinear

**op** - Variable in class javax.media.jai.PropertySourceImpl

**OP\_COMPUTE\_BOUND** - Static variable in class javax.media.jai.OpImage  
 A constant indicating that an operation is likely to spend its time mainly performing computation.

**OP\_IO\_BOUND** - Static variable in class javax.media.jai.OpImage  
 A constant indicating that an operation is likely to spend its time mainly performing local I/O.

**OP\_NETWORK\_BOUND** - Static variable in class javax.media.jai.OpImage  
 A constant indicating that an operation is likely to spend its time mainly performing network I/O.

**opArgList** - Variable in class javax.media.jai.RenderableGraphics

**opDescsName** - Variable in class javax.media.jai.OperationRegistry  
 A Hashtable of all the OperationDescriptors, hashed by the operation name of the OperationDescriptors.

**OperationDescriptor** - interface javax.media.jai.OperationDescriptor.  
 This interface provides a comprehensive description of a specific image operation.

**OperationDescriptorImpl** - class javax.media.jai.OperationDescriptorImpl.  
This class provides a concrete implementation of the `OperationDescriptor` interface, and is suitable for subclassing.

**OperationDescriptorImpl(String[], Class[])** - Constructor for class javax.media.jai.OperationDescriptorImpl  
Constructor for operations that supports only the rendered mode and requires no parameters.

**OperationDescriptorImpl(String[], Class[], Class[])** - Constructor for class javax.media.jai.OperationDescriptorImpl  
Constructor for operations that supports either the rendered or the renderable or both modes and requires no parameters.

**OperationDescriptorImpl(String[], Class[], Class[], Class[], String[], Object[])** - Constructor for class javax.media.jai.OperationDescriptorImpl  
Constructor.

**OperationDescriptorImpl(String[], Class[], String[], Object[])** - Constructor for class javax.media.jai.OperationDescriptorImpl  
Constructor for operations that supports either the rendered or the renderable or both modes and requires no sources.

**OperationDescriptorImpl(String[], int)** - Constructor for class javax.media.jai.OperationDescriptorImpl  
Constructor for operations that support the rendered mode and possibly the renderable mode and require no parameters.

**OperationDescriptorImpl(String[], int, Class[], String[], Object[])** - Constructor for class javax.media.jai.OperationDescriptorImpl  
Constructor for operations that supports either the rendered or the renderable or both modes.

**OperationGraph** - class javax.media.jai.OperationGraph.  
OperationGraph manages a list of products belonging to a particular operation descriptor.

**OperationGraph()** - Constructor for class javax.media.jai.OperationGraph  
Constructs an OperationGraph.

**operationName** - Variable in class javax.media.jai.RenderedOp  
The name of the operation this node represents.

**operationName** - Variable in class javax.media.jai.RenderableOp  
The name of the operation this node represents.

**operationRegistry** - Variable in class javax.media.jai.JAI

**OperationRegistry** - class javax.media.jai.OperationRegistry.  
A class implementing the translation of operation names into instances of `RenderedImageFactory`, `ContextualRenderedImageFactory` and `CollectionImageFactory`.

**OperationRegistry()** - Constructor for class javax.media.jai.OperationRegistry  
Default Constructor.

**operations** - Variable in class javax.media.jai.ProductOperationGraph  
A Vector of RIF implementations.

**OpImage** - class javax.media.jai.OpImage.  
The parent class for all imaging operations.

**OpImage(RenderedImage, BorderExtender, TileCache, ImageLayout, boolean)** - Constructor for class javax.media.jai.OpImage  
Constructs an OpImage, given a single source image.

**OpImage(RenderedImage, RenderedImage, BorderExtender, BorderExtender, TileCache, ImageLayout, boolean)** - Constructor for class javax.media.jai.OpImage  
Constructs an OpImage, given two source images.

**OpImage(Vector, BorderExtender[], TileCache, ImageLayout, boolean)** - Constructor for class javax.media.jai.OpImage  
Constructs an OpImage, given a Vector of sources.

**opName** - Variable in class javax.media.jai.CollectionOp  
The name of the operation this node represents.

**OrConstDescriptor** - class javax.media.jai.operator.OrConstDescriptor.  
An `OperationDescriptor` describing the "OrConst" operation.

**OrConstDescriptor()** - Constructor for class javax.media.jai.operator.OrConstDescriptor  
Constructor.

**orderedCIFOperations** - Variable in class javax.media.jai.OperationGraph

**OrderedDitherDescriptor** - class javax.media.jai.operator.OrderedDitherDescriptor.  
An `OperationDescriptor` describing the "OrderedDither" operation.

**OrderedDitherDescriptor()** - Constructor for class javax.media.jai.operator.OrderedDitherDescriptor  
Constructor.

**orderedProducts** - Variable in class javax.media.jai.ProductOperationGraph  
A cached version of the ordered product list

**orderedRIFOperations** - Variable in class javax.media.jai.OperationGraph  
The cached list of ordered operations for RIF/CIF

**orderList(Vector)** - Method in class javax.media.jai.OperationGraph  
Performs a topological sort on the set of image factories.

**OrDescriptor** - class javax.media.jai.operator.OrDescriptor.  
An `OperationDescriptor` describing the "Or" operation.

**OrDescriptor()** - Constructor for class javax.media.jai.operator.OrDescriptor  
Constructor.

**origin** - Variable in class javax.media.jai.TiledImageGraphics

**origin** - Variable in class javax.media.jai.RenderableGraphics

**originX** - Variable in class javax.media.jai.widget.ImageCanvas  
The pixel to display in the upper left corner of the canvas.

**originY** - Variable in class javax.media.jai.widget.ImageCanvas  
The pixel to display in the upper left corner of the canvas.

**output** - Variable in class com.sun.media.jai.codec.ImageEncoderImpl  
The OutputStream associated with this ImageEncoder.

**output8BitGray** - Variable in class com.sun.media.jai.codec.PNGDecodeParam

**overlapBounds** - Variable in class javax.media.jai.TiledImage

**OverlayDescriptor** - class javax.media.jai.operator.OverlayDescriptor.  
An `OperationDescriptor` describing the "Overlay" operation.

**OverlayDescriptor()** - Constructor for class javax.media.jai.operator.OverlayDescriptor  
Constructor.

**overlayPixels(WritableRaster, RenderedImage, Area)** - Method in class javax.media.jai.TiledImage  
Overlays a set of pixels described by an `Area` from an image onto a tile.

**overlayPixels(WritableRaster, RenderedImage, Rectangle)** - Method in class javax.media.jai.TiledImage  
Overlays a rectangular area of pixels from an image onto a tile.

**overlayPixels(WritableRaster, RenderedImage, Rectangle, int[])** - Method in class javax.media.jai.TiledImage  
Overlays a set of pixels described by a bitmask onto a tile.

---

## P

**packageName** - Static variable in class javax.media.jai.JaiI18N

**packageName** - Static variable in class javax.media.jai.iterator.JaiI18N

**packageName** - Static variable in class javax.media.jai.operator.JaiI18N

**packageName** - Static variable in class javax.media.jai.widget.JaiI18N

**packageName** - Static variable in class com.sun.media.jai.codec.JaiI18N

**padX** - Variable in class javax.media.jai.widget.ImageCanvas  
used to center image in it's container

**padY** - Variable in class javax.media.jai.widget.ImageCanvas

**paethPredictor(int, int, int)** - Static method in class com.sun.media.jai.codec.PNGEncodeParam  
The Paeth predictor routine used in PNG encoding.

**PAGE\_MASK** - Static variable in class com.sun.media.jai.codec.FileSeekableStream

**PAGE\_SHIFT** - Static variable in class com.sun.media.jai.codec.FileSeekableStream

**PAGE\_SIZE** - Static variable in class com.sun.media.jai.codec.FileSeekableStream

**pageBuf** - Variable in class com.sun.media.jai.codec.FileSeekableStream

**paint** - Variable in class javax.media.jai.TiledImageGraphics

**paint** - Variable in class javax.media.jai.RenderableGraphics

**PAINT\_MODE** - Static variable in class javax.media.jai.TiledImageGraphics

**paint(Graphics)** - Method in class javax.media.jai.widget.ImageCanvas  
Paint the image onto a Graphics object.

**paintMode** - Variable in class javax.media.jai.TiledImageGraphics

**palette** - Variable in class com.sun.media.jai.codec.PNGEncodeParam.Palette

**paletteHistogram** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**paletteHistogramSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**paletteSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam.Palette

**panelHeight** - Variable in class javax.media.jai.widget.ScrollingImagePanel  
The height of the panel.

**panelWidth** - Variable in class javax.media.jai.widget.ScrollingImagePanel  
The width of the panel.

**param** - Variable in class com.sun.media.jai.codec.ImageDecoderImpl  
The ImageDecodeParam object associated with this ImageEncoder.

**param** - Variable in class com.sun.media.jai.codec.ImageEncoderImpl  
The ImageEncodeParam object associated with this ImageEncoder.

**paramBlock** - Variable in class javax.media.jai.RenderedOp  
The input arguments for this operation, including sources and/or parameters.

**paramBlock** - Variable in class javax.media.jai.RenderableOp  
The input arguments for this operation, including sources and/or parameters.

**paramClasses** - Variable in class javax.media.jai.ParameterBlockJAI  
The Class types of the parameters.

**paramClasses** - Variable in class javax.media.jai.OperationDescriptorImpl  
An array of Classes that describe the types of parameters required by this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.RenderableDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.AWTImageDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.ImageFunctionDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.LookupDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.WarpDescriptor  
The parameter class types for the "Warp" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.GradientMagnitudeDescriptor  
The parameter class types for the GradientMagnitude operation.

**paramClasses** - Static variable in class javax.media.jai.operator.PNGDescriptor  
The parameter class types for the "PNG" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.BorderDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.ConvolveDescriptor  
The parameter class types for the Convolve operation.

**paramClasses** - Static variable in class javax.media.jai.operator.ErrorDiffusionDescriptor  
The parameter class types for the "ErrorDiffusion" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.XorConstDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.CompositeDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.ThresholdDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.CropDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.SubtractFromConstDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.PeriodicShiftDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.BandSelectDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.TIFFDescriptor  
The parameter class types for the "TIFF" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.FormatDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.ExtremaDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.AndConstDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.SubtractConstDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.AddConstToCollectionDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.OrConstDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.ClampDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.MeanDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.FileLoadDescriptor  
The parameter class types for the "FileLoad" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.BoxFilterDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.GIFDescriptor  
The parameter class types for the "GIF" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.StreamDescriptor  
The parameter class types for the "Stream" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.BandCombineDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.IIPResolutionDescriptor  
The parameter class types for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.MultiplyConstDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.MatchCDFDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.OrderedDitherDescriptor  
The parameter class types for the "OrderedDither" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.ConstantDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.TransposeDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.AddConstDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.BMPDescriptor  
The parameter class types for the "BMP" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.TranslateDescriptor  
The parameter class types for the "Translate" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.DFTDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.ShearDescriptor  
The parameter class types for the "Shear" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.PatternDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.HistogramDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.AffineDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.DivideByConstDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.URLDescriptor  
The parameter class types for the "URL" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.RescaleDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.RotateDescriptor  
The parameter class types for the "Rotate" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.PiecewiseDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.IDFTDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.IIPDescriptor  
The parameter class types for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.DivideIntoConstDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.PNMDescriptor  
The parameter class types for the "PNM" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.EncodeDescriptor  
The parameter class types for the "Encode" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.MedianFilterDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.FileStoreDescriptor  
The parameter class types for the "FileStore" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.JPEGDescriptor  
The parameter class types for the "JPEG" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.ScaleDescriptor  
The parameter class list for this operation.

**paramClasses** - Static variable in class javax.media.jai.operator.FPXDescriptor  
The parameter class types for the "FPX" operation.

**paramClasses** - Static variable in class javax.media.jai.operator.ColorConvertDescriptor  
The parameter class list for this operation.

**paramDefaults** - Variable in class javax.media.jai.OperationDescriptorImpl  
An array of Objects that define the default values of the parameters of this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.RenderableDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.AWTImageDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.ImageFunctionDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.LookupDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.WarpDescriptor  
The parameter default values for the "Warp" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.GradientMagnitudeDescriptor  
The parameter default values for the GradientMagnitude operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.PNGDescriptor  
The parameter default values for the "PNG" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.BorderDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.ConvolveDescriptor  
The parameter default values for the Convolve operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.ErrorDiffusionDescriptor  
The parameter default values for the "ErrorDiffusion" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.XorConstDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.CompositeDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.ThresholdDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.CropDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.SubtractFromConstDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.PeriodicShiftDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.BandSelectDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.TIFFDescriptor  
The parameter default values for the "TIFF" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.FormatDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.ExtremaDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.AndConstDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.SubtractConstDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.AddConstToCollectionDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.OrConstDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.ClampDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.MeanDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.FileLoadDescriptor  
The parameter default values for the "FileLoad" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.BoxFilterDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.GIFDescriptor  
The parameter default values for the "GIF" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.StreamDescriptor  
The parameter default values for the "Stream" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.BandCombineDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.IIPResolutionDescriptor  
The parameter default values for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.MultiplyConstDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.MatchCDFDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.OrderedDitherDescriptor  
The parameter default values for the "OrderedDither" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.ConstantDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.TransposeDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.AddConstDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.BMPDescriptor  
The parameter default values for the "BMP" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.TranslateDescriptor  
The parameter default values for the "Translate" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.DFTDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.ShearDescriptor  
The parameter default values for the "Shear" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.PatternDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.HistogramDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.AffineDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.DivideByConstDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.URLDescriptor  
The parameter default values for the "URL" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.RescaleDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.RotateDescriptor  
The parameter default values for the "Rotate" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.PiecewiseDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.IDFTDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.IIPDescriptor  
The parameter default values for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.DivideIntoConstDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.PNMDescriptor  
The parameter default values for the "PNM" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.EncodeDescriptor  
The parameter default values for the "Encode" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.MedianFilterDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.FileStoreDescriptor  
The parameter default values for the "FileStore" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.JPEGDescriptor  
The parameter default values for the "JPEG" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.ScaleDescriptor  
The parameter default value list for this operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.FPXDescriptor  
The parameter default values for the "FPX" operation.

**paramDefaults** - Static variable in class javax.media.jai.operator.ColorConvertDescriptor  
The parameter default value list for this operation.

**ParameterBlockJAI** - class javax.media.jai.ParameterBlockJAI.  
A convenience subclass of ParameterBlock that allows the use of default parameter values and getting/setting parameters by name.

**ParameterBlockJAI(OperationDescriptor)** - Constructor for class javax.media.jai.ParameterBlockJAI  
Constructs a ParameterBlockJAI for use with an operation described by a particular OperationDescriptor.

**ParameterBlockJAI(String)** - Constructor for class javax.media.jai.ParameterBlockJAI  
Constructs a ParameterBlockJAI for a particular operation by name.

**paramNames** - Variable in class javax.media.jai.OperationDescriptorImpl  
An array of Strings that are the localized parameter names of this operation.

**paramNames** - Static variable in class javax.media.jai.operator.RenderableDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.AWTImageDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.ImageFunctionDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.LookupDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.WarpDescriptor  
The parameter names for the "Warp" operation.

**paramNames** - Static variable in class javax.media.jai.operator.GradientMagnitudeDescriptor  
The parameter names for the GradientMagnitude operation.

**paramNames** - Static variable in class javax.media.jai.operator.PNGDescriptor  
The parameter names for the "PNG" operation.

**paramNames** - Static variable in class javax.media.jai.operator.BorderDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.ConvolveDescriptor  
The parameter names for the Convolve operation.

**paramNames** - Static variable in class javax.media.jai.operator.ErrorDiffusionDescriptor  
The parameter names for the "ErrorDiffusion" operation.

**paramNames** - Static variable in class javax.media.jai.operator.XorConstDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.CompositeDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.ThresholdDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.CropDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.SubtractFromConstDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.PeriodicShiftDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.BandSelectDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.TIFFDescriptor  
The parameter names for the "TIFF" operation.

**paramNames** - Static variable in class javax.media.jai.operator.FormatDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.ExtremaDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.AndConstDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.SubtractConstDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.AddConstToCollectionDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.OrConstDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.ClampDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.MeanDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.FileLoadDescriptor  
The parameter names for the "FileLoad" operation.

**paramNames** - Static variable in class javax.media.jai.operator.BoxFilterDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.GIFDescriptor  
The parameter names for the "GIF" operation.

**paramNames** - Static variable in class javax.media.jai.operator.StreamDescriptor  
The parameter names for the "Stream" operation.

**paramNames** - Static variable in class javax.media.jai.operator.BandCombineDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.IIPResolutionDescriptor  
The parameter names for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.MultiplyConstDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.MatchCDFDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.OrderedDitherDescriptor  
The parameter names for the "OrderedDither" operation.

**paramNames** - Static variable in class javax.media.jai.operator.ConstantDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.TransposeDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.AddConstDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.BMPDescriptor  
The parameter names for the "BMP" operation.

**paramNames** - Static variable in class javax.media.jai.operator.TranslateDescriptor  
The parameter names for the "Translate" operation.

**paramNames** - Static variable in class javax.media.jai.operator.DFTDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.ShearDescriptor  
The parameter names for the "Shear" operation.

**paramNames** - Static variable in class javax.media.jai.operator.PatternDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.HistogramDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.AffineDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.DivideByConstDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.URLDescriptor  
The parameter names for the "URL" operation.

**paramNames** - Static variable in class javax.media.jai.operator.RescaleDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.RotateDescriptor  
The parameter names for the "Rotate" operation.

**paramNames** - Static variable in class javax.media.jai.operator.PiecewiseDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.IDFTDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.IIPDescriptor  
The parameter names for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.DivideIntoConstDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.PNMDescriptor  
The parameter names for the "PNM" operation.

**paramNames** - Static variable in class javax.media.jai.operator.EncodeDescriptor  
The parameter names for the "Encode" operation.

**paramNames** - Static variable in class javax.media.jai.operator.MedianFilterDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.FileStoreDescriptor  
The parameter names for the "FileStore" operation.

**paramNames** - Static variable in class javax.media.jai.operator.JPEGDescriptor  
The parameter names for the "JPEG" operation.

**paramNames** - Static variable in class javax.media.jai.operator.ScaleDescriptor  
The parameter name list for this operation.

**paramNames** - Static variable in class javax.media.jai.operator.FPXDescriptor  
The parameter names for the "FPX" operation.

**paramNames** - Static variable in class javax.media.jai.operator.ColorConvertDescriptor  
The parameter name list for this operation.

**parent** - Variable in class javax.media.jai.SnapshotProxy  
The parent Snapshot to which we forward getTile() calls.

**parent** - Variable in class javax.media.jai.Snapshot  
The creator of this image.

**parent** - Variable in class javax.media.jai.TiledImage

**PartialOrderNode** - class javax.media.jai.PartialOrderNode.  
A node in a directed graph of operations.

**PartialOrderNode(Object, String)** - Constructor for class javax.media.jai.PartialOrderNode  
Constructs an PartialOrderNode with given associated data.

**path** - Variable in class javax.media.jai.Storage

**PatternDescriptor** - class javax.media.jai.operator.PatternDescriptor.  
An OperationDescriptor describing the "Pattern" operation.

**PatternDescriptor()** - Constructor for class javax.media.jai.operator.PatternDescriptor  
Constructor.

**performGammaCorrection** - Variable in class com.sun.media.jai.codec.PNGDecodeParam

**performImageOp(RenderedImageFactory, ParameterBlock, int, RenderingHints)** - Method in class javax.media.jai.ROI  
Transforms an ROI using an imaging operation.

**performImageOp(String, ParameterBlock, int, RenderingHints)** - Method in class javax.media.jai.ROI  
Transforms an ROI using an imaging operation.

**PeriodicShiftDescriptor** - class javax.media.jai.operator.PeriodicShiftDescriptor.  
An OperationDescriptor describing the "PeriodicShift" operation.

**PeriodicShiftDescriptor()** - Constructor for class javax.media.jai.operator.PeriodicShiftDescriptor  
Constructor.

**permitInPlaceOperation()** - Method in class javax.media.jai.PointOpImage  
Causes a flag to be set to indicate that in-place operation should be permitted if the image bounds, tile grid offset, tile dimensions, and SampleModels of the source and destination images are compatible.

**PERSPECTIVE\_DIVIDE\_EPSILON** - Static variable in class javax.media.jai.PerspectiveTransform

**PerspectiveTransform** - class javax.media.jai.PerspectiveTransform.  
A 2D perspective (or projective) transform, used by various OpImages.

**PerspectiveTransform()** - Constructor for class javax.media.jai.PerspectiveTransform  
Constructs an identity PerspectiveTransform.

**PerspectiveTransform(AffineTransform)** - Constructor for class javax.media.jai.PerspectiveTransform  
Constructs a new PerspectiveTransform with the same effect as an existing AffineTransform.

**PerspectiveTransform(double[])** - Constructor for class javax.media.jai.PerspectiveTransform  
Constructs a new PerspectiveTransform from a one-dimensional array of 9 doubles, in row-major order.

**PerspectiveTransform(double[][])** - Constructor for class javax.media.jai.PerspectiveTransform  
Constructs a new PerspectiveTransform from a two-dimensional array of doubles.

**PerspectiveTransform(double, double, double, double, double, double, double, double, double)** - Constructor for class javax.media.jai.PerspectiveTransform  
Constructs a new PerspectiveTransform from 9 doubles.

**PerspectiveTransform(float[])** - Constructor for class javax.media.jai.PerspectiveTransform  
Constructs a new PerspectiveTransform from a one-dimensional array of 9 floats, in row-major order.

**PerspectiveTransform(float[][])** - Constructor for class javax.media.jai.PerspectiveTransform  
Constructs a new PerspectiveTransform from a two-dimensional array of floats.

**PerspectiveTransform(float, float, float, float, float, float, float, float, float)** - Constructor for class javax.media.jai.PerspectiveTransform  
Constructs a new PerspectiveTransform from 9 floats.

**pg** - Variable in class javax.media.jai.PropertySourceImpl

**PhaseDescriptor** - class javax.media.jai.operator.PhaseDescriptor.  
An OperationDescriptor describing the "Phase" operation.

**PhaseDescriptor()** - Constructor for class javax.media.jai.operator.PhaseDescriptor  
Constructor.

**PhasePropertyGenerator** - class javax.media.jai.operator.PhasePropertyGenerator.  
This property generator computes the properties for the operation "Phase" dynamically.

**PhasePropertyGenerator()** - Constructor for class javax.media.jai.operator.PhasePropertyGenerator  
Constructor.

**physicalDimension** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**physicalDimensionSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**PiecewiseDescriptor** - class javax.media.jai.operator.PiecewiseDescriptor.  
 An `OperationDescriptor` describing the "Piecewise" operation.

**PiecewiseDescriptor()** - Constructor for class javax.media.jai.operator.PiecewiseDescriptor  
 Constructor.

**pixelStride** - Variable in class javax.media.jai.RasterFormatTag

**pixelStride** - Variable in class javax.media.jai.RasterAccessor  
 The pixel stride of the image data in each data array

**PlanarImage** - class javax.media.jai.PlanarImage.  
 The fundamental base class representing two-dimensional images.

**PlanarImage()** - Constructor for class javax.media.jai.PlanarImage  
 The default constructor.

**PNG\_FILTER\_AVERAGE** - Static variable in class com.sun.media.jai.codec.PNGEncodeParam  
 Constant for use in filtering.

**PNG\_FILTER\_NONE** - Static variable in class com.sun.media.jai.codec.PNGEncodeParam  
 Constant for use in filtering.

**PNG\_FILTER\_PAETH** - Static variable in class com.sun.media.jai.codec.PNGEncodeParam  
 Constant for use in filtering.

**PNG\_FILTER\_SUB** - Static variable in class com.sun.media.jai.codec.PNGEncodeParam  
 Constant for use in filtering.

**PNG\_FILTER\_UP** - Static variable in class com.sun.media.jai.codec.PNGEncodeParam  
 Constant for use in filtering.

**PNGDecodeParam** - class com.sun.media.jai.codec.PNGDecodeParam.  
 An instance of `ImageDecodeParam` for decoding images in the PNG format.

**PNGDecodeParam()** - Constructor for class com.sun.media.jai.codec.PNGDecodeParam  
 Constructs a default instance of `PNGDecodeParam`.

**PNGDescriptor** - class javax.media.jai.operator.PNGDescriptor.  
 An `OperationDescriptor` describing the "PNG" operation.

**PNGDescriptor()** - Constructor for class javax.media.jai.operator.PNGDescriptor  
 Constructor.

**PNGEncodeParam** - class com.sun.media.jai.codec.PNGEncodeParam.  
 An instance of `ImageEncodeParam` for encoding images in the PNG format.

**PNGEncodeParam.Gray** - class com.sun.media.jai.codec.PNGEncodeParam.Gray.

**PNGEncodeParam.Gray()** - Constructor for class com.sun.media.jai.codec.PNGEncodeParam.Gray  
 Constructs an instance of `PNGEncodeParam.Gray`.

**PNGEncodeParam.Palette** - class com.sun.media.jai.codec.PNGEncodeParam.Palette.

**PNGEncodeParam.Palette()** - Constructor for class com.sun.media.jai.codec.PNGEncodeParam.Palette  
 Constructs an instance of `PNGEncodeParam.Palette`.

**PNGEncodeParam.RGB** - class com.sun.media.jai.codec.PNGEncodeParam.RGB.

**PNGEncodeParam.RGB()** - Constructor for class com.sun.media.jai.codec.PNGEncodeParam.RGB  
 Constructs an instance of `PNGEncodeParam.RGB`.

**PNGEncodeParam()** - Constructor for class com.sun.media.jai.codec.PNGEncodeParam

**PNGSuggestedPaletteEntry** - class com.sun.media.jai.codec.PNGSuggestedPaletteEntry.  
 A class representing the fields of a PNG suggested palette entry.

**PNGSuggestedPaletteEntry()** - Constructor for class com.sun.media.jai.codec.PNGSuggestedPaletteEntry

**PNMDescriptor** - class javax.media.jai.operator.PNMDescriptor.  
 An `OperationDescriptor` describing the "PNM" operation.

**PNMDescriptor()** - Constructor for class javax.media.jai.operator.PNMDescriptor  
 Constructor.

**PNMEncodeParam** - class com.sun.media.jai.codec.PNMEncodeParam.  
 An instance of `ImageEncodeParam` for encoding images in the PNM format.

**PNMEncodeParam()** - Constructor for class com.sun.media.jai.codec.PNMEncodeParam  
 Constructs a `PNMEncodeParam` object with default values for parameters.

**pointer** - Variable in class com.sun.media.jai.codec.ForwardSeekableStream  
 The current position.

**pointer** - Variable in class com.sun.media.jai.codec.SegmentedSeekableStream

**pointer** - Variable in class com.sun.media.jai.codec.ByteArraySeekableStream  
 The current output position.

**pointer** - Variable in class com.sun.media.jai.codec.MemoryCacheSeekableStream  
 Position of first unread byte.

**pointer** - Variable in class com.sun.media.jai.codec.FileCacheSeekableStream  
Next byte to be read.

**pointer** - Variable in class com.sun.media.jai.codec.FileSeekableStream

**PointOpImage** - class javax.media.jai.PointOpImage.  
An abstract base class for image operators that require only the (x, y) pixel from each source image in order to compute the destination pixel (x, y).

**PointOpImage(RenderedImage, RenderedImage, RenderedImage, TileCache, ImageLayout, boolean)** - Constructor for class javax.media.jai.PointOpImage  
Constructs a PointOpImage with three source images.

**PointOpImage(RenderedImage, RenderedImage, TileCache, ImageLayout, boolean)** - Constructor for class javax.media.jai.PointOpImage  
Constructs a PointOpImage with two source images.

**PointOpImage(RenderedImage, TileCache, ImageLayout, boolean)** - Constructor for class javax.media.jai.PointOpImage  
Constructs a PointOpImage with one source image.

**PointOpImage(Vector, TileCache, ImageLayout, boolean)** - Constructor for class javax.media.jai.PointOpImage  
Constructs a PointOpImage with a Vector of RenderedImages as its sources.

**PolarToComplexDescriptor** - class javax.media.jai.operator.PolarToComplexDescriptor.  
An OperationDescriptor describing the "PolarToComplex" operation.

**PolarToComplexDescriptor()** - Constructor for class javax.media.jai.operator.PolarToComplexDescriptor  
Constructor.

**PolarToComplexPropertyGenerator** - class javax.media.jai.operator.PolarToComplexPropertyGenerator.  
This property generator computes the properties for the operation "PolarToComplex" dynamically.

**PolarToComplexPropertyGenerator()** - Constructor for class javax.media.jai.operator.PolarToComplexPropertyGenerator  
Constructor.

**poly** - Variable in class javax.media.jai.ROIShape.PolyShape  
The internal polygon.

**POLYGON\_CONCAVE** - Static variable in class javax.media.jai.ROIShape.PolyShape  
A concave polygon (simple or non-simple).

**POLYGON\_CONVEX** - Static variable in class javax.media.jai.ROIShape.PolyShape  
A convex polygon.

**POLYGON\_DEGENERATE** - Static variable in class javax.media.jai.ROIShape.PolyShape  
A degenerate polygon, i.e., all vertices equal or on the same line.

**POLYGON\_UNCLASSIFIED** - Static variable in class javax.media.jai.ROIShape.PolyShape  
A polygon which has yet to be classified as one of the following types.

**polygonToRunLengthList(Rectangle, Polygon)** - Method in class javax.media.jai.ROIShape  
Convert a Polygon into a LinkedList of Rectangles representing run lengths of pixels contained within the Polygon.

**postScaleX** - Variable in class javax.media.jai.WarpPolynomial  
A scaling factor applied to the result of the X polynomial evaluation which compensates for the input scaling, so that the correctly scaled result is achieved.

**postScaleY** - Variable in class javax.media.jai.WarpPolynomial  
A scaling factor applied to the result of the Y polynomial evaluation which compensates for the input scaling, so that the correctly scaled result is achieved.

**PRECISION\_BITS** - Static variable in class javax.media.jai.InterpolationBicubic2

**PRECISION\_BITS** - Static variable in class javax.media.jai.InterpolationBicubic

**precisionBits** - Variable in class javax.media.jai.InterpolationTable  
The number of fractional bits used to describe filter coefficients.

**preConcatenate(AffineTransform)** - Method in class javax.media.jai.PerspectiveTransform  
Pre-concatenates a given AffineTransform to this transform.

**preConcatenate(PerspectiveTransform)** - Method in class javax.media.jai.PerspectiveTransform  
Pre-concatenates a given PerspectiveTransform to this transform.

**prefetchTiles(PlanarImage, Point[])** - Method in interface javax.media.jai.TileScheduler  
Hints to the TileScheduler that the given tiles from the given PlanarImage might be needed in the near future.

**prefetchTiles(Point[])** - Method in class javax.media.jai.PlanarImage  
Hints that the given tiles might be needed in the near future.

**prefetchTiles(Point[])** - Method in class javax.media.jai.RenderedOp  
Renders the node if it has not already been rendered.

**prefetchTiles(Point[])** - Method in class javax.media.jai.OpImage  
Hints that the given tiles might be needed in the near future.

**preScaleX** - Variable in class javax.media.jai.WarpPolynomial  
A scaling factor applied to input (dest) x coordinates to which may improve computational accuracy.

**preScaleY** - Variable in class javax.media.jai.WarpPolynomial  
A scaling factor applied to input (dest) y coordinates to which may improve computational accuracy.

**prev** - Variable in class javax.media.jai.Snapshot  
The previous Snapshot in a doubly-linked list.

**prevBand()** - Method in interface javax.media.jai.iterator.RookIter  
Sets the iterator to the previous band in the image.

**prevBandDone()** - Method in interface javax.media.jai.iterator.RookIter  
Sets the iterator to the previous band in the image, and returns true if the min band has been exceeded.

**prevLine()** - Method in interface javax.media.jai.iterator.RookIter  
Sets the iterator to the previous line of the image.

**prevLineDone()** - Method in interface javax.media.jai.iterator.RookIter  
Sets the iterator to the previous line in the image, and returns true if the top row of the bounding rectangle has been passed.

**prevPixel()** - Method in interface javax.media.jai.iterator.RookIter  
Sets the iterator to the previous pixel in the image (that is, move leftward).

**prevPixelDone()** - Method in interface javax.media.jai.iterator.RookIter  
Sets the iterator to the previous pixel in the image (that is, move leftward).

**print\_tile(int, int)** - Method in class javax.media.jai.PlanarImage  
For debugging.

**print()** - Method in class javax.media.jai.PlanarImage  
For debugging.

**printBounds()** - Method in class javax.media.jai.PlanarImage  
For debugging.

**prodPref** - Variable in class javax.media.jai.RegistryInitData

**product** - Variable in class javax.media.jai.Storage

**product** - Variable in class javax.media.jai.Store

**ProductOperationGraph** - class javax.media.jai.ProductOperationGraph.  
ProductOperationGraph manages a list of operations (image factories) belonging to a particular product.

**ProductOperationGraph()** - Constructor for class javax.media.jai.ProductOperationGraph  
Constructs an ProductOperationGraph.

**productPrefs** - Variable in class javax.media.jai.OperationRegistry  
A Hashtable of all the product preferences, hashed by the operation name descriptor that the products belong to.

**products** - Variable in class javax.media.jai.OperationRegistry  
A Hashtable of all the products, hashed by the operation name of the OperationDescriptor to which they belong.

**properties** - Variable in class javax.media.jai.PlanarImage  
A Hashtable containing the image properties.

**properties** - Variable in class javax.media.jai.OperationRegistry

**properties** - Variable in class javax.media.jai.TiledImageGraphics

**properties** - Variable in class javax.media.jai.StatisticsOpImage  
A Hashtable containing all the properties generated, hashed by property names.

**PropertyGenerator** - interface javax.media.jai.PropertyGenerator.  
An interface through which properties may be computed dynamically with respect to an environment of pre-existing properties.

**PropertyGeneratorFromSource** - class javax.media.jai.PropertyGeneratorFromSource.  
A class that implements the PropertyGenerator interface.

**PropertyGeneratorFromSource(int, String)** - Constructor for class javax.media.jai.PropertyGeneratorFromSource

**propertyName** - Variable in class javax.media.jai.PropertyGeneratorFromSource

**propertyNames** - Variable in class javax.media.jai.RemoteImage  
Locally cached version of properties.

**PropertySource** - interface javax.media.jai.PropertySource.  
An interface encapsulating the set of operations involved in identifying and reading properties.

**PropertySourceImpl** - class javax.media.jai.PropertySourceImpl.  
A class that implements the PropertySource interface.

**PropertySourceImpl(Vector, Vector, Vector, Hashtable, RenderableOp)** - Constructor for class javax.media.jai.PropertySourceImpl

**PropertySourceImpl(Vector, Vector, Vector, Hashtable, RenderedOp)** - Constructor for class javax.media.jai.PropertySourceImpl

**propNames** - Variable in class javax.media.jai.OperationRegistry

**propNames** - Variable in class javax.media.jai.PropertySourceImpl

---

## Q

**qTab** - Variable in class com.sun.media.jai.codec.JPEGEncodeParam

**qTabSet** - Variable in class com.sun.media.jai.codec.JPEGEncodeParam

**qTabSlot** - Variable in class com.sun.media.jai.codec.JPEGEncodeParam

**qual** - Variable in class com.sun.media.jai.codec.JPEGEncodeParam

**qualitySet** - Variable in class com.sun.media.jai.codec.JPEGEncodeParam

**queueOpArg(String, Class[], Object[])** - Method in class javax.media.jai.RenderableGraphics  
Queue a Graphics2D operation and its argument list in the linked list of operations and arguments.

---

## R

**RandomIter** - interface javax.media.jai.iterator.RandomIter.

An iterator that allows random read-only access to any sample within its bounding rectangle.

**RandomIterFactory** - class javax.media.jai.iterator.RandomIterFactory.

A factory class to instantiate instances of the RandomIter and WritableRandomIter interfaces on sources of type Raster, RenderedImage, and WritableRenderedImage.

**RandomIterFactory()** - Constructor for class javax.media.jai.iterator.RandomIterFactory

Prevent this class from ever being instantiated.

**raster** - Variable in class javax.media.jai.RasterAccessor

The raster that is the source of pixel data.

**RasterAccessor** - class javax.media.jai.RasterAccessor.

An adapter class for presenting image data in a ComponentSampleModel format, even if the data isn't stored that way.

**RasterAccessor(Raster, Rectangle, RasterFormatTag, ColorModel)** - Constructor for class

javax.media.jai.RasterAccessor

Constructs a RasterAccessor object out of a Raster, Rectangle and formatTagID returned from

RasterFormat.findCompatibleTag().

**RasterFactory** - class javax.media.jai.RasterFactory.

A convenience class for the construction of various types of WritableRaster and SampleModel objects.

**RasterFactory()** - Constructor for class javax.media.jai.RasterFactory

**RasterFormatTag** - class javax.media.jai.RasterFormatTag.

This class encapsulates the information needed for RasterAccessor to understand how a Raster is laid out.

**RasterFormatTag(SampleModel, int)** - Constructor for class javax.media.jai.RasterFormatTag

Constructs a RasterFormatTag given a sampleModel and a formatTagID.

**rationalTolerance** - Static variable in class javax.media.jai.ScaleOpImage

**raw** - Variable in class com.sun.media.jai.codec.PNMEncodeParam

**READ\_CACHE\_LIMIT** - Static variable in class com.sun.media.jai.codec.FileSeekableStream

**read()** - Method in class com.sun.media.jai.codec.SeekableStream

Reads the next byte of data from the input stream.

**read()** - Method in class com.sun.media.jai.codec.ForwardSeekableStream

Forwards the request to the real InputStream.

**read()** - Method in class com.sun.media.jai.codec.SegmentedSeekableStream

Reads the next byte of data from the input stream.

**read()** - Method in class com.sun.media.jai.codec.ByteArraySeekableStream

Reads the next byte of data from the input array.

**read()** - Method in class com.sun.media.jai.codec.MemoryCacheSeekableStream

Reads the next byte of data from the input stream.

**read()** - Method in class com.sun.media.jai.codec.FileCacheSeekableStream

Reads the next byte of data from the input stream.

**read()** - Method in class com.sun.media.jai.codec.FileSeekableStream

Forwards the request to the real File.

**read(byte[], int, int)** - Method in class com.sun.media.jai.codec.SeekableStream

Reads up to len bytes of data from the input stream into an array of bytes.

**read(byte[], int, int)** - Method in class com.sun.media.jai.codec.ForwardSeekableStream  
Forwards the request to the real `InputStream`.

**read(byte[], int, int)** - Method in class com.sun.media.jai.codec.SegmentedSeekableStream  
Reads up to `len` bytes of data from the input stream into an array of bytes.

**read(byte[], int, int)** - Method in class com.sun.media.jai.codec.ByteArraySeekableStream  
Copies up to `len` bytes of data from the input array into an array of bytes.

**read(byte[], int, int)** - Method in class com.sun.media.jai.codec.MemoryCacheSeekableStream  
Reads up to `len` bytes of data from the input stream into an array of bytes.

**read(byte[], int, int)** - Method in class com.sun.media.jai.codec.FileCacheSeekableStream  
Reads up to `len` bytes of data from the input stream into an array of bytes.

**read(byte[], int, int)** - Method in class com.sun.media.jai.codec.FileSeekableStream  
Forwards the request to the real `File`.

**readBoolean()** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads a `boolean` from this stream.

**readByte()** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads a signed eight-bit value from this stream.

**readChar()** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads a Unicode character from this stream.

**readCharLE()** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads a Unicode character from this stream in little-endian order.

**readDouble()** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads a `double` from this stream.

**readDouble(SeekableStream)** - Method in class com.sun.media.jai.codec.TIFFDirectory

**readDoubleLE()** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads a `double` from this stream in little-endian order.

**readExternal(ObjectInput)** - Method in class javax.media.jai.OperationRegistry  
Restores the contents of the registry from an `ObjectInput` which was previously written using the `writeExternal` method.

**readFloat()** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads a `float` from this stream.

**readFloat(SeekableStream)** - Method in class com.sun.media.jai.codec.TIFFDirectory

**readFloatLE()** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads a `float` from this stream in little-endian order.

**readFully(byte[])** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads `b.length` bytes from this stream into the byte array, starting at the current stream pointer.

**readFully(byte[], int, int)** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads exactly `len` bytes from this stream into the byte array, starting at the current stream pointer.

**readInitFile(Reader)** - Static method in class javax.media.jai.OperationRegistry  
Reads the registry initialization file and stores the information read into memory data structures.

**readInt()** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads a signed 32-bit integer from this stream.

**readInt(SeekableStream)** - Method in class com.sun.media.jai.codec.TIFFDirectory

**readIntLE()** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads a signed 32-bit integer from this stream in little-endian order.

**readLine()** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads the next line of text from this stream.

**readLong()** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads a signed 64-bit integer from this stream.

**readLong(SeekableStream)** - Method in class com.sun.media.jai.codec.TIFFDirectory

**readLongLE()** - Method in class com.sun.media.jai.codec.SeekableStream  
Reads a signed 64-bit integer from this stream in little-endian order.

**readObject(ObjectInputStream)** - Method in class javax.media.jai.ImageLayout  
Deserialize the `ImageLayout`.

**readObject(ObjectInputStream)** - Method in class javax.media.jai.RenderedOp  
Deserialize the `RenderedOp`.

**readObject(ObjectInputStream)** - Method in class javax.media.jai.RenderableOp  
Deserialize the `RenderableOp`.

**readObject(ObjectInputStream)** - Method in class javax.media.jai.ROI  
Deserialize the `ROI`.

**readObject(ObjectInputStream)** - Method in class javax.media.jai.MultiResolutionRenderableImage  
Deserialize the `MultiResolutionRenderableImage`.

**readObject(ObjectInputStream)** - Method in class javax.media.jai.LookupTableJAI  
Deserialize the `LookupTableJAI`.

**readObject(ObjectInputStream)** - Method in class javax.media.jai.ROIShape  
 Deserialize the ROIShape.

**readPage(long)** - Method in class com.sun.media.jai.codec.FileSeekableStream

**readShort()** - Method in class com.sun.media.jai.codec.SeekableStream  
 Reads a signed 16-bit number from this stream.

**readShort(SeekableStream)** - Method in class com.sun.media.jai.codec.TIFFDirectory

**readShortLE()** - Method in class com.sun.media.jai.codec.SeekableStream  
 Reads a signed 16-bit number from this stream in little-endian order.

**readUnsignedByte()** - Method in class com.sun.media.jai.codec.SeekableStream  
 Reads an unsigned eight-bit number from this stream.

**readUnsignedInt()** - Method in class com.sun.media.jai.codec.SeekableStream  
 Reads an unsigned 32-bit integer from this stream.

**readUnsignedInt(SeekableStream)** - Method in class com.sun.media.jai.codec.TIFFDirectory

**readUnsignedInt(SeekableStream, boolean)** - Static method in class com.sun.media.jai.codec.TIFFDirectory

**readUnsignedIntLE()** - Method in class com.sun.media.jai.codec.SeekableStream  
 Reads an unsigned 32-bit integer from this stream in little-endian order.

**readUnsignedShort()** - Method in class com.sun.media.jai.codec.SeekableStream  
 Reads an unsigned 16-bit number from this stream.

**readUnsignedShort(SeekableStream)** - Method in class com.sun.media.jai.codec.TIFFDirectory

**readUnsignedShort(SeekableStream, boolean)** - Static method in class com.sun.media.jai.codec.TIFFDirectory

**readUnsignedShortLE()** - Method in class com.sun.media.jai.codec.SeekableStream  
 Reads an unsigned 16-bit number from this stream in little-endian order.

**readUntil(long)** - Method in class com.sun.media.jai.codec.MemoryCacheSeekableStream  
 Ensures that at least pos bytes are cached, or the end of the source is reached.

**readUntil(long)** - Method in class com.sun.media.jai.codec.FileCacheSeekableStream  
 Ensures that at least pos bytes are cached, or the end of the source is reached.

**readUTF()** - Method in class com.sun.media.jai.codec.SeekableStream  
 Reads a string from this stream.

**REAL\_TO\_COMPLEX** - Static variable in class javax.media.jai.operator.DFTDescriptor  
 A flag indicating that the source data are real and the destination data complex.

**rectangleListToBitmask(LinkedList, Rectangle, int[][])** - Static method in class javax.media.jai.ROIShape  
 Convert a LinkedList of Rectangles into an array of integers representing a bit mask.

**rectHeight** - Variable in class javax.media.jai.RasterAccessor  
 The height of the rectangle this RasterAccessor addresses.

**RectIter** - interface javax.media.jai.iterator.RectIter.  
 An iterator for traversing a read-only image in top-to-bottom, left-to-right order.

**RectIterFactory** - class javax.media.jai.iterator.RectIterFactory.  
 A factory class to instantiate instances of the RectIter and WritableRectIter interfaces on sources of type Raster, RenderedImage, and WritableRenderedImage.

**RectIterFactory()** - Constructor for class javax.media.jai.iterator.RectIterFactory  
 Prevent this class from ever being instantiated.

**rectWidth** - Variable in class javax.media.jai.RasterAccessor  
 The width of the rectangle this RasterAccessor addresses.

**rectX** - Variable in class javax.media.jai.RasterAccessor  
 The x of the rectangle this RasterAccessor addresses.

**rectY** - Variable in class javax.media.jai.RasterAccessor  
 The y of the rectangle this RasterAccessor addresses.

**red** - Variable in class com.sun.media.jai.codec.PNGSuggestedPaletteEntry  
 The red color value of the entry.

**registerCIF(String, String, CollectionImageFactory)** - Method in class javax.media.jai.OperationRegistry  
 Registers a CIF with a particular product and operation.

**registerCIFNoLock(String, String, CollectionImageFactory)** - Method in class javax.media.jai.OperationRegistry

**registerCodec(ImageCodec)** - Static method in class com.sun.media.jai.codec.ImageCodec  
 Associates an ImageCodec with its format name, as determined by its getFormatName() method.

**registerCRIF(String, ContextualRenderedImageFactory)** - Method in class javax.media.jai.OperationRegistry  
 Registers a CRIF under a particular operation.

**registerCRIFNoLock(String, ContextualRenderedImageFactory)** - Method in class javax.media.jai.OperationRegistry

**registerName** - Variable in class javax.media.jai.Storage

**registerOperationDescriptor(OperationDescriptor, String)** - Method in class javax.media.jai.OperationRegistry  
Registers an OperationDescriptor with the registry.

**registerOperationDescriptorNoLock(OperationDescriptor, String)** - Method in class javax.media.jai.OperationRegistry

**registerRIF(String, String, RenderedImageFactory)** - Method in class javax.media.jai.OperationRegistry  
Registers a RIF with a particular product and operation.

**registerRIFNoLock(String, String, RenderedImageFactory)** - Method in class javax.media.jai.OperationRegistry

**registry** - Variable in class javax.media.jai.CollectionOp  
The OperationRegistry that is used to render this node.

**RegistryInitData** - class javax.media.jai.RegistryInitData

**RegistryInitData(Hashtable, Hashtable, Hashtable, Hashtable, Vector, Vector, Vector)** - Constructor for class javax.media.jai.RegistryInitData

**releaseWritableTile(int, int)** - Method in class javax.media.jai.WritableRenderedImageAdapter  
Relinquish the right to write to a tile.

**releaseWritableTile(int, int)** - Method in class javax.media.jai.TiledImage  
Indicates that a writer is done updating a tile.

**remoteImage** - Variable in class javax.media.jai.RemoteImage  
The RMIImage our data will come from.

**RemoteImage** - class javax.media.jai.RemoteImage.  
A sub-class of PlanarImage which represents an image on a remote server machine.

**RemoteImage(String, RenderableOp, RenderContext)** - Constructor for class javax.media.jai.RemoteImage  
Constructs a RemoteImage from a RenderableOp and RenderContext.

**RemoteImage(String, RenderedImage)** - Constructor for class javax.media.jai.RemoteImage  
Constructs a RemoteImage from a RenderedImage.

**RemoteImage(String, RenderedOp)** - Constructor for class javax.media.jai.RemoteImage  
Constructs a RemoteImage from a RenderedOp, i.e., an imaging directed acyclic graph (DAG).

**remove(float)** - Method in class javax.media.jai.ImageSequence  
Removes the SequentialImage that contains the specified time stamp from this collection.

**remove(Object)** - Method in class javax.media.jai.CollectionImage  
Removes the specified object from this collection.

**remove(Object)** - Method in class javax.media.jai.ImageSequence  
Removes the SequentialImage that contains the specified camera position from this collection.

**remove(Object)** - Method in class javax.media.jai.ImageStack  
Removes the CoordinateImage that contains the specified coordinate from this collection.

**remove(Object)** - Method in class javax.media.jai.CollectionOp  
Removes the specified object from this collection.

**remove(PlanarImage)** - Method in class javax.media.jai.ImageSequence  
Removes the SequentialImage that contains the specified image from this collection.

**remove(PlanarImage)** - Method in class javax.media.jai.ImageStack  
Removes the CoordinateImage that contains the specified image from this collection.

**remove(RenderedImage, int, int)** - Method in interface javax.media.jai.TileCache  
Advises the cache that a tile is no longer needed.

**removeAll(Collection)** - Method in class javax.media.jai.CollectionImage  
Removes all this collection's elements that are also contained in the specified collection.

**removeAll(Collection)** - Method in class javax.media.jai.CollectionOp  
Removes all this collection's elements that are also contained in the specified collection.

**removeAllPrivateChunks()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Remove all private chunks associated with this parameter instance.

**removeCIF(CollectionImageFactory)** - Method in class javax.media.jai.OperationGraph  
Removes a CIF from an OperationGraph.

**removeEdge(PartialOrderNode)** - Method in class javax.media.jai.PartialOrderNode  
Removes a directed edge from the graph.

**removePropertyGenerator(PropertyGenerator)** - Method in class javax.media.jai.PropertySourceImpl

**removePropertyGenerator(String, PropertyGenerator)** - Method in class javax.media.jai.OperationRegistry  
Removes a PropertyGenerator from its association with a particular OperationDescriptor in the registry.

**removeRenderingHint(RenderingHints.Key)** - Method in class javax.media.jai.JAI  
Removes the hint value associated with a given key in this JAI instance.

**removeRIF(RenderedImageFactory)** - Method in class javax.media.jai.OperationGraph  
Removes a RIF from an OperationGraph.

**removeSink(PlanarImage)** - Method in class javax.media.jai.PlanarImage  
Removes a PlanarImage sink from the list of sinks.

**removeSink(PlanarImage)** - Method in class javax.media.jai.RenderedOp  
Renders the node if it has not already been rendered, and removes a PlanarImage sink from the list of sinks of the rendered image.

**removeSinks()** - Method in class `javax.media.jai.PlanarImage`  
Clears the list of sinks.

**removeSource(PlanarImage)** - Method in class `javax.media.jai.PlanarImage`  
Removes a `PlanarImage` source from the list of sources.

**removeSource(PlanarImage)** - Method in class `javax.media.jai.RenderedOp`  
Renders the node if it has not already been rendered, and removes a `PlanarImage` source from the list of sources of the rendered image.

**removeSources()** - Method in class `javax.media.jai.PlanarImage`  
Clears the list of sources.

**removeSources()** - Method in class `javax.media.jai.RenderedOp`  
Removes all the sources stored in the `ParameterBlock` of this node.

**removeSuppressedProps(PropertyGenerator)** - Method in class `javax.media.jai.PropertySourceImpl`

**removeTileObserver(TileObserver)** - Method in class `javax.media.jai.WritableRenderedImageAdapter`  
Remove an observer.

**removeTileObserver(TileObserver)** - Method in class `javax.media.jai.TiledImage`  
Informs this `TiledImage` that a particular `TileObserver` no longer wishes to receive updates on tile writability status.

**removeTiles(RenderedImage)** - Method in interface `javax.media.jai.TileCache`  
Advises the cache that all tiles associated with a given image are no longer needed.

**removeUnsafeToCopyPrivateChunks()** - Method in class `com.sun.media.jai.codec.PNGEncodeParam`  
Remove all private chunks associated with this parameter instance whose 'safe-to-copy' bit is not set.

**removeViewportListener(ViewportListener)** - Method in class `javax.media.jai.widget.ScrollingImagePanel`  
Removes the specified `ViewportListener`

**RenderableDescriptor** - class `javax.media.jai.operator.RenderableDescriptor`.  
An `OperationDescriptor` describing the "Renderable" operation.

**RenderableDescriptor()** - Constructor for class `javax.media.jai.operator.RenderableDescriptor`  
Constructor.

**RenderableGraphics** - class `javax.media.jai.RenderableGraphics`.  
An implementation of `Graphics2D` with `RenderableImage` semantics.

**RenderableGraphics(Rectangle2D)** - Constructor for class `javax.media.jai.RenderableGraphics`  
Constructs a `RenderableGraphics` given a bounding `Rectangle2D`.

**RenderableGraphics(Rectangle2D, LinkedList, Point, Graphics2D)** - Constructor for class `javax.media.jai.RenderableGraphics`  
Constructs a `RenderableGraphics` given a bounding `Rectangle2D`, an origin, and a `Graphics2D` object from which to initialize the `RenderableGraphics` state.

**RenderableImageAdapter** - class `javax.media.jai.RenderableImageAdapter`.  
An adapter class for externally-generated `RenderableImages`.

**RenderableImageAdapter(RenderableImage)** - Constructor for class `javax.media.jai.RenderableImageAdapter`  
Constructs a `RenderableImageAdapter` from a `RenderableImage`.

**RenderableOp** - class `javax.media.jai.RenderableOp`.  
A JAI version of `RenderableImageOp`.

**RenderableOp(OperationRegistry, String, ParameterBlock)** - Constructor for class `javax.media.jai.RenderableOp`  
Constructs a `RenderableOp` given the name of the operation to be performed and a `ParameterBlock` containing `RenderableImage` sources and other parameters.

**RenderableOp(String, ParameterBlock)** - Constructor for class `javax.media.jai.RenderableOp`  
Constructs a `RenderableOp` given the name of the operation to be performed and a `ParameterBlock` containing `RenderableImage` sources and other parameters.

**renderableSourceClasses** - Variable in class `javax.media.jai.OperationDescriptorImpl`  
An array of `Classes` that describe the types of sources required by this operation in the renderable mode.

**RenderedImageAdapter** - class `javax.media.jai.RenderedImageAdapter`.  
A `PlanarImage` wrapper for a non-writable `RenderedImage`.

**RenderedImageAdapter(RenderedImage)** - Constructor for class `javax.media.jai.RenderedImageAdapter`  
Constructs a `RenderedImageAdapter`.

**RenderedOp** - class `javax.media.jai.RenderedOp`.  
A node in a rendered imaging chain.

**RenderedOp(OperationRegistry, String, ParameterBlock, RenderingHints)** - Constructor for class `javax.media.jai.RenderedOp`  
Constructs a `RenderedOp` that will be used to instantiate a particular rendered operation from a given operation registry, an operation name, a `ParameterBlock`, and a set of rendering hints.

**RenderedOp(String, ParameterBlock, RenderingHints)** - Constructor for class `javax.media.jai.RenderedOp`  
Constructs a `RenderedOp` that will be used to instantiate a particular rendered operation from a given operation registry, an operation name, a `ParameterBlock`, and a set of rendering hints.

**renderedSource** - Variable in class `javax.media.jai.MultiResolutionRenderableImage`  
An array of `RenderedImage` sources.

**renderHints** - Variable in class `javax.media.jai.RenderedOp`  
The rendering hints to use for this operation.

**renderingHints** - Variable in class javax.media.jai.TiledImageGraphics

**renderingHints** - Variable in class javax.media.jai.RenderableGraphics

**renderingHints** - Variable in class javax.media.jai.JAI

**requestField(int)** - Method in class javax.media.jai.RemoteImage

Causes an instance variable of the remote object to be cached locally, retrying indefinitely with a default timeout of 1 second.

**requestField(int, int, int)** - Method in class javax.media.jai.RemoteImage

Causes an instance variable of the remote object to be cached locally, retrying a given number of times with a given timeout.

**RescaleDescriptor** - class javax.media.jai.operator.RescaleDescriptor.

An `OperationDescriptor` describing the "Rescale" operation.

**RescaleDescriptor()** - Constructor for class javax.media.jai.operator.RescaleDescriptor  
Constructor.

**reset()** - Method in class com.sun.media.jai.codec.SeekableStream

Returns the file position to its position at the time of the immediately previous call to the `mark()` method.

**reset()** - Method in class com.sun.media.jai.codec.ForwardSeekableStream

Forwards the request to the real `InputStream`.

**reset()** - Method in class com.sun.media.jai.codec.FileSeekableStream

Returns the file position to its position at the time of the immediately previous call to the `mark()` method.

**resolution** - Variable in class com.sun.media.jai.codec.FPXDecodeParam

**resources** - Variable in class javax.media.jai.OperationDescriptorImpl

The resource tags and their corresponding data, stored as an two-dimensional `String` array.

**resources** - Static variable in class javax.media.jai.operator.RenderableDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

**resources** - Static variable in class javax.media.jai.operator.DCTDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

**resources** - Static variable in class javax.media.jai.operator.PolarToComplexDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

**resources** - Static variable in class javax.media.jai.operator.AWTImageDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

**resources** - Static variable in class javax.media.jai.operator.ImageFunctionDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

**resources** - Static variable in class javax.media.jai.operator.LookupDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

**resources** - Static variable in class javax.media.jai.operator.WarpDescriptor

The resource strings that provide the general documentation and specify the parameter list for the "Warp" operation.

**resources** - Static variable in class javax.media.jai.operator.GradientMagnitudeDescriptor

The resource strings that provide the general documentation and specify the parameter list for the GradientMagnitude operation.

**resources** - Static variable in class javax.media.jai.operator.IDCTDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

**resources** - Static variable in class javax.media.jai.operator.PNGDescriptor

The resource strings that provide the general documentation and specify the parameter list for the "PNG" operation.

**resources** - Static variable in class javax.media.jai.operator.BorderDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

**resources** - Static variable in class javax.media.jai.operator.ConvolveDescriptor

The resource strings that provide the general documentation and specify the parameter list for a Convolve operation.

**resources** - Static variable in class javax.media.jai.operator.ErrorDiffusionDescriptor

The resource strings that provide the general documentation and specify the parameter list for the "ErrorDiffusion" operation.

**resources** - Static variable in class javax.media.jai.operator.MultiplyDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

**resources** - Static variable in class javax.media.jai.operator.MagnitudeDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

**resources** - Static variable in class javax.media.jai.operator.XorConstDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

**resources** - Static variable in class javax.media.jai.operator.CompositeDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

**resources** - Static variable in class javax.media.jai.operator.AndDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

**resources** - Static variable in class javax.media.jai.operator.SubtractDescriptor

The resource strings that provide the general documentation and specify the parameter list for this operation.

[illegible]

[illegible]

**resources** - Static variable in class javax.media.jai.operator.OrDescriptor  
The resource strings that provide the general documentation and specify the parameter list for this operation.

**retainAll(Collection)** - Method in class javax.media.jai.CollectionImage  
Retains only the elements in this collection that are contained in the specified collection.

**retainAll(Collection)** - Method in class javax.media.jai.CollectionOp  
Retains only the elements in this collection that are contained in the specified collection.

**RGBABits16** - Static variable in class com.sun.media.jai.codec.ImageCodec

**RGBABits32** - Static variable in class com.sun.media.jai.codec.ImageCodec

**RGBABits8** - Static variable in class com.sun.media.jai.codec.ImageCodec

**RGBBits16** - Static variable in class com.sun.media.jai.codec.ImageCodec

**RGBBits32** - Static variable in class com.sun.media.jai.codec.ImageCodec

**RGBBits8** - Static variable in class com.sun.media.jai.codec.ImageCodec

**rifcount** - Variable in class javax.media.jai.OperationRegistry  
A count to give a number to each registered RIF.

**RIFoperations** - Variable in class javax.media.jai.OperationGraph  
A Vector of RIF implementations.

**rifPref** - Variable in class javax.media.jai.RegistryInitData

**rifPrefs** - Variable in class javax.media.jai.OperationRegistry  
A Hashtable of all the RIF preferences, hashed by the operation name that the RIF belongs to.

**rifs** - Variable in class javax.media.jai.OperationRegistry  
A Hashtable of all the RIFs, hashed by a filename that uniquely identifies each registered RIF.

**rifsByName** - Variable in class javax.media.jai.OperationRegistry  
A Hashtable of all the unique RIF filenames, hashed by the RIF they represent.

**rifTable** - Variable in class javax.media.jai.RegistryInitData

**rightPadding** - Variable in class javax.media.jai.Interpolation  
The number of pixels lying to the right of the interpolation kernel key position.

**rightPadding** - Variable in class javax.media.jai.AreaOpImage  
The number of source pixels needed to the right of the central pixel.

**roi** - Variable in class javax.media.jai.StatisticsOpImage  
The region of interest over which to compute the statistics.

**ROI** - class javax.media.jai.ROI  
The parent class for representations of a region of interest of an image.

**ROI()** - Constructor for class javax.media.jai.ROI  
The default constructor.

**ROI(RenderedImage)** - Constructor for class javax.media.jai.ROI  
Constructs an ROI from a RenderedImage.

**ROI(RenderedImage, int)** - Constructor for class javax.media.jai.ROI  
Constructs an ROI from a RenderedImage.

**ROIShape** - class javax.media.jai.ROIShape.  
A class representing a region of interest within an image as a Shape.

**ROIShape.PolyShape** - class javax.media.jai.ROIShape.PolyShape.  
Instance inner class used for scan conversion of a polygonal Shape.

**ROIShape.PolyShape.PolyEdge** - class javax.media.jai.ROIShape.PolyShape.PolyEdge.  
Inner class representing a polygon edge.

**ROIShape.PolyShape.PolyEdge(ROIShape.PolyShape, double, double, int)** - Constructor for class javax.media.jai.ROIShape.PolyShape.PolyEdge  
Construct a PolyEdge object.

**ROIShape.PolyShape(ROIShape, Polygon, Rectangle)** - Constructor for class javax.media.jai.ROIShape.PolyShape  
Constructs a new PolyShape.

**ROIShape(Area)** - Constructor for class javax.media.jai.ROIShape  
Constructs an ROIShape from an Area.

**ROIShape(Shape)** - Constructor for class javax.media.jai.ROIShape  
Constructs an ROIShape from a Shape.

**RookIter** - interface javax.media.jai.iterator.RookIter.  
An iterator for traversing a read-only image using arbitrary up-down and left-right moves.

**RookIterFactory** - class javax.media.jai.iterator.RookIterFactory.  
A factory class to instantiate instances of the RookIter and WritableRookIter interfaces on sources of type Raster, RenderedImage, and WritableRenderedImage.

**RookIterFactory()** - Constructor for class javax.media.jai.iterator.RookIterFactory  
Prevent this class from ever being instantiated.

**ROTATE\_180** - Static variable in class javax.media.jai.operator.TransposeDescriptor

**ROTATE\_270** - Static variable in class javax.media.jai.operator.TransposeDescriptor

**ROTATE\_90** - Static variable in class javax.media.jai.operator.TransposeDescriptor

**rotate(double)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**rotate(double)** - Method in class javax.media.jai.PerspectiveTransform  
Concatenates this transform with a rotation transformation.

**rotate(double)** - Method in class javax.media.jai.TiledImageGraphics

**rotate(double)** - Method in class javax.media.jai.RenderableGraphics

**rotate(double, double, double)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**rotate(double, double, double)** - Method in class javax.media.jai.PerspectiveTransform  
Concatenates this transform with a translated rotation transformation.

**rotate(double, double, double)** - Method in class javax.media.jai.TiledImageGraphics

**rotate(double, double, double)** - Method in class javax.media.jai.RenderableGraphics

**RotateDescriptor** - class javax.media.jai.operator.RotateDescriptor.  
An `OperationDescriptor` describing the "Rotate" operation.

**RotateDescriptor()** - Constructor for class javax.media.jai.operator.RotateDescriptor  
Constructor.

**rotatedKernel** - Variable in class javax.media.jai.KernelJAI  
Variable to cache a copy of the rotated kernel

**RotatePropertyGenerator** - class javax.media.jai.operator.RotatePropertyGenerator.  
This property generator computes the properties for the operation "Rotate" dynamically.

**RotatePropertyGenerator()** - Constructor for class javax.media.jai.operator.RotatePropertyGenerator  
Constructor.

**round** - Variable in class javax.media.jai.InterpolationTable  
The number 1/2 with precisionBits of fractional precision.

**round** - Variable in class javax.media.jai.InterpolationBilinear

**round2** - Variable in class javax.media.jai.InterpolationBilinear

**rpad** - Variable in class javax.media.jai.ScaleOpImage

**rstInterval** - Variable in class com.sun.media.jai.codec.JPEGEncodeParam

**ruileBuf** - Variable in class com.sun.media.jai.codec.SeekableStream

---

## S

**sameBounds** - Variable in class javax.media.jai.PointOpImage

**sameTileGrid** - Variable in class javax.media.jai.PointOpImage

**SAMPLE\_MODEL\_MASK** - Static variable in class javax.media.jai.ImageLayout  
A bitmask to specify the validity of sampleModel.

**sampleDepth** - Variable in class com.sun.media.jai.codec.PNGSuggestedPaletteEntry  
The depth of the color samples.

**sampleModel** - Variable in class javax.media.jai.ImageLayout  
The image's `SampleModel`.

**sampleModel** - Variable in class javax.media.jai.PlanarImage  
The image's `SampleModel`.

**sampleModel** - Variable in class javax.media.jai.widget.ImageCanvas  
The image's `SampleModel`.

**scale(double, double)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**scale(double, double)** - Method in class javax.media.jai.PerspectiveTransform  
Concatenates this transform with a scaling transformation.

**scale(double, double)** - Method in class javax.media.jai.TiledImageGraphics

**scale(double, double)** - Method in class javax.media.jai.RenderableGraphics

**ScaleDescriptor** - class javax.media.jai.operator.ScaleDescriptor.  
An OperationDescriptor describing the "Scale" operation.

**ScaleDescriptor()** - Constructor for class javax.media.jai.operator.ScaleDescriptor  
Constructor.

**ScaleOpImage** - class javax.media.jai.ScaleOpImage.  
A class extending WarpOpImage for use by further extension classes that perform image scaling.

**ScaleOpImage(RenderedImage, BorderExtender, TileCache, ImageLayout, float, float, float, float, Interpolation, boolean)** - Constructor for class javax.media.jai.ScaleOpImage  
Constructs a ScaleOpImage from a RenderedImage source, an optional BorderExtender, x and y scale and translation factors, and an Interpolation object.

**ScalePropertyGenerator** - class javax.media.jai.operator.ScalePropertyGenerator.  
This property generator computes the properties for the operation "Scale" dynamically.

**ScalePropertyGenerator()** - Constructor for class javax.media.jai.operator.ScalePropertyGenerator  
Constructor.

**scaleX** - Variable in class javax.media.jai.ScaleOpImage  
The horizontal scale factor.

**scaleXRational** - Variable in class javax.media.jai.ScaleOpImage  
Rational representations

**scaleXRationalDenom** - Variable in class javax.media.jai.ScaleOpImage

**scaleXRationalNum** - Variable in class javax.media.jai.ScaleOpImage

**scaleY** - Variable in class javax.media.jai.ScaleOpImage  
The vertical scale factor.

**scaleYRational** - Variable in class javax.media.jai.ScaleOpImage  
Rational representations

**scaleYRationalDenom** - Variable in class javax.media.jai.ScaleOpImage

**scaleYRationalNum** - Variable in class javax.media.jai.ScaleOpImage

**SCALING\_DIMENSIONS** - Static variable in class javax.media.jai.operator.DFTDescriptor  
A flag indicating that the transform is to be scaled by the product of its dimensions.

**SCALING\_NONE** - Static variable in class javax.media.jai.operator.DFTDescriptor  
A flag indicating that the transform is not to be scaled.

**SCALING\_UNITARY** - Static variable in class javax.media.jai.operator.DFTDescriptor  
A flag indicating that the transform is to be scaled by the square root of the product of its dimensions.

**scanConcave(LinkedList)** - Method in class javax.media.jai.ROIShape.PolyShape  
Perform scan conversion of a concave polygon.

**scanConvex(LinkedList)** - Method in class javax.media.jai.ROIShape.PolyShape  
Perform scan conversion of a convex polygon.

**scanlineStride** - Variable in class javax.media.jai.RasterAccessor  
The scanline stride of the image data in each data array

**scanSegment(int, double, double)** - Method in class javax.media.jai.ROIShape.PolyShape  
Return a Rectangle for the supplied line and abscissa end points.

**scheduleTile(OpImage, int, int)** - Method in interface javax.media.jai.TileScheduler  
Schedules a tile for computation.

**scheduleTiles(OpImage, Point[])** - Method in interface javax.media.jai.TileScheduler  
Schedules a list of tiles for computation.

**ScrollingImagePanel** - class javax.media.jai.widget.ScrollingImagePanel.  
An extension of java.awt.Panel that contains an ImageCanvas and vertical and horizontal scrollbars.

**ScrollingImagePanel(RenderedImage, int, int)** - Constructor for class javax.media.jai.widget.ScrollingImagePanel  
Constructs a ScrollingImagePanel of a given size for a given RenderedImage.

**SECTOR\_MASK** - Static variable in class com.sun.media.jai.codec.MemoryCacheSeekableStream  
A mask to determine the offset within a sector.

**SECTOR\_SHIFT** - Static variable in class com.sun.media.jai.codec.MemoryCacheSeekableStream  
Log<sub>2</sub> of the sector size.

**SECTOR\_SIZE** - Static variable in class com.sun.media.jai.codec.MemoryCacheSeekableStream  
The sector size.

**sectors** - Variable in class com.sun.media.jai.codec.MemoryCacheSeekableStream  
Number of sectors stored.

**SectorStreamSegmentMapper** - class com.sun.media.jai.codec.SectorStreamSegmentMapper.  
An implementation of the `StreamSegmentMapper` interface for segments of equal length.  
**SectorStreamSegmentMapper(long[], int, int)** - Constructor for class com.sun.media.jai.codec.SectorStreamSegmentMapper

**seek(long)** - Method in class com.sun.media.jai.codec.SeekableStream  
Sets the offset, measured from the beginning of this stream, at which the next read occurs.  
**seek(long)** - Method in class com.sun.media.jai.codec.ForwardSeekableStream  
Seeks forward to the given position in the stream.  
**seek(long)** - Method in class com.sun.media.jai.codec.SegmentedSeekableStream  
Sets the offset, measured from the beginning of this stream, at which the next read occurs.  
**seek(long)** - Method in class com.sun.media.jai.codec.ByteArraySeekableStream  
Sets the offset, measured from the beginning of this stream, at which the next read occurs.  
**seek(long)** - Method in class com.sun.media.jai.codec.MemoryCacheSeekableStream  
Sets the file-pointer offset, measured from the beginning of this file, at which the next read occurs.  
**seek(long)** - Method in class com.sun.media.jai.codec.FileCacheSeekableStream  
Sets the file-pointer offset, measured from the beginning of this file, at which the next read occurs.  
**seek(long)** - Method in class com.sun.media.jai.codec.FileSeekableStream

**SeekableStream** - class com.sun.media.jai.codec.SeekableStream.  
An abstract subclass of `java.io.InputStream` that allows seeking within the input, similar to the `RandomAccessFile` class.  
**SeekableStream()** - Constructor for class com.sun.media.jai.codec.SeekableStream

**SegmentedSeekableStream** - class com.sun.media.jai.codec.SegmentedSeekableStream.  
A `SegmentedSeekableStream` provides a view of a subset of another `SeekableStream` consisting of a series of segments with given starting positions in the source stream and lengths.

**SegmentedSeekableStream(SeekableStream, long[], int[], boolean)** - Constructor for class com.sun.media.jai.codec.SegmentedSeekableStream  
Constructs a `SegmentedSeekableStream` given a `SeekableStream` as input, a list of the starting positions and lengths of the segments of the source stream, and a `boolean` indicating whether the output `SegmentedSeekableStream` should support seeking backwards.

**SegmentedSeekableStream(SeekableStream, long[], int, int, boolean)** - Constructor for class com.sun.media.jai.codec.SegmentedSeekableStream  
Constructs a `SegmentedSeekableStream` given a `SeekableStream` as input, a list of the starting positions of the segments of the source stream, the common length of each segment, the total length of the segments and a `boolean` indicating whether the output `SegmentedSeekableStream` should support seeking backwards.

**SegmentedSeekableStream(SeekableStream, StreamSegmentMapper, boolean)** - Constructor for class com.sun.media.jai.codec.SegmentedSeekableStream  
Constructs a `SegmentedSeekableStream` given a `SeekableStream` as input, an instance of `StreamSegmentMapper`, and a `boolean` indicating whether the output `SegmentedSeekableStream` should support seeking backwards.

**segmentLength** - Variable in class com.sun.media.jai.codec.SectorStreamSegmentMapper

**segmentLength** - Variable in class com.sun.media.jai.codec.StreamSegment

**segmentLengths** - Variable in class com.sun.media.jai.codec.StreamSegmentMapperImpl

**segmentPositions** - Variable in class com.sun.media.jai.codec.StreamSegmentMapperImpl

**segmentPositions** - Variable in class com.sun.media.jai.codec.SectorStreamSegmentMapper

**SequentialImage** - class javax.media.jai.SequentialImage.  
A class representing an image that is associated with a time stamp and a camera position.  
**SequentialImage(PlanarImage, float, Object)** - Constructor for class javax.media.jai.SequentialImage

**set(byte, String)** - Method in class javax.media.jai.ParameterBlockJAI  
Sets a named parameter to a byte value.  
**set(char, String)** - Method in class javax.media.jai.ParameterBlockJAI  
Sets a named parameter to a char value.  
**set(double, String)** - Method in class javax.media.jai.ParameterBlockJAI  
Sets a named parameter to a double value.  
**set(float, String)** - Method in class javax.media.jai.ParameterBlockJAI  
Sets a named parameter to a float value.  
**set(int, String)** - Method in class javax.media.jai.ParameterBlockJAI  
Sets a named parameter to an int value.

**set(long, String)** - Method in class javax.media.jai.ParameterBlockJAI  
Sets a named parameter to a long value.

**set(Object, String)** - Method in class javax.media.jai.ParameterBlockJAI  
Sets a named parameter to an Object value.

**set(RenderedImage)** - Method in class javax.media.jai.TiledImage  
Overlays a given `RenderedImage` on top of the current contents of the `TiledImage`.

**set(RenderedImage)** - Method in class javax.media.jai.widget.ImageCanvas  
Changes the source image to a new `RenderedImage`.

**set(RenderedImage)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Sets the panel to display the specified image

**set(RenderedImage, ROI)** - Method in class javax.media.jai.TiledImage  
Overlays a given `RenderedImage` on top of the current contents of the `TiledImage`.

**set(short, String)** - Method in class javax.media.jai.ParameterBlockJAI  
Sets a named parameter to a short value.

**setBackground(Color)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**setBackground(Color)** - Method in class javax.media.jai.TiledImageGraphics

**setBackground(Color)** - Method in class javax.media.jai.RenderableGraphics

**setBackgroundGray(int)** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Gray  
Sets the suggested gray level of the background.

**setBackgroundPaletteIndex(int)** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Palette  
Sets the palette index of the suggested background color.

**setBackgroundRGB(int[])** - Method in class com.sun.media.jai.codec.PNGEncodeParam.RGB  
Sets the RGB value of the suggested background color.

**setBitDepth(int)** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Sets the desired bit depth of an image.

**setBitDepth(int)** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Palette  
Sets the desired bit depth for a palette image.

**setBitDepth(int)** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Gray  
Sets the desired bit depth for a grayscale image.

**setBitDepth(int)** - Method in class com.sun.media.jai.codec.PNGEncodeParam.RGB  
Sets the desired bit depth for an RGB image.

**setBitShift(int)** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Gray  
Sets the desired bit shift for a grayscale image.

**setBounds(int, int, int, int)** - Method in class javax.media.jai.widget.ImageCanvas  
Records a new size.

**setBounds(int, int, int, int)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Called by the AWT during instantiation and when events such as resize occur.

**setCenter(int, int)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Set the center of the image to the given coordinates of the scroll window.

**setChromaQTable(int[])** - Method in class com.sun.media.jai.codec.JPEGEncodeParam  
Sets the quantization table to be used for chrominance data.

**setChromaticity(float[])** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Sets the white point and primary chromaticities in CIE (x, y) space.

**setChromaticity(float, float, float, float, float, float, float, float)** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
A convenience method that calls the array version.

**setCIFPreference(CollectionImageFactory, CollectionImageFactory)** - Method in class javax.media.jai.OperationGraph  
Sets a preference between two CIFs.

**setCIFPreference(String, String, CollectionImageFactory, CollectionImageFactory)** - Method in class javax.media.jai.OperationRegistry  
Sets a preference between two CIFs within the same product.

**setCIFPreferenceNoLock(String, String, CollectionImageFactory, CollectionImageFactory)** - Method in class javax.media.jai.OperationRegistry

**setClip(int, int, int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**setClip(int, int, int, int)** - Method in class javax.media.jai.TiledImageGraphics

**setClip(int, int, int, int)** - Method in class javax.media.jai.RenderableGraphics

**setClip(Shape)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**setClip(Shape)** - Method in class javax.media.jai.TiledImageGraphics

**setClip(Shape)** - Method in class javax.media.jai.RenderableGraphics

**setColor(Color)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**setColor(Color)** - Method in class javax.media.jai.TiledImageGraphics

**setColor(Color)** - Method in class javax.media.jai.RenderableGraphics

**setColorModel(ColorModel)** - Method in class javax.media.jai.ImageLayout  
Sets colorModel to the supplied value and marks it as valid.

**setComposite(Composite)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**setComposite(Composite)** - Method in class javax.media.jai.TiledImageGraphics

**setComposite(Composite)** - Method in class javax.media.jai.RenderableGraphics

**setCompressed(boolean)** - Method in class com.sun.media.jai.codec.BMPEncodeParam  
If set, the data will be written out compressed, if possible.

**setCompressedText(String[])** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Sets the text strings to be stored in compressed form with this image.

**setCompression(int)** - Method in class com.sun.media.jai.codec.TIFFEncodeParam  
Specifies the type of compression to be used.

**setCopyInDegree(int)** - Method in class javax.media.jai.PartialOrderNode  
Sets the copy in-degree of this node.

**setData(Raster)** - Method in class javax.media.jai.WritableRenderedImageAdapter  
Set a rectangular region of the image to the contents of raster.

**setData(Raster)** - Method in class javax.media.jai.TiledImage  
Sets a region of a TiledImage to be a copy of a supplied Raster.

**setData(Raster, ROI)** - Method in class javax.media.jai.TiledImage  
Sets a region of a TiledImage to be a copy of a supplied Raster.

**setDataElements(int, int, int, int, Object, DataBuffer)** - Method in class javax.media.jai.ComponentSampleModelJAI  
Sets the data for a rectangle of pixels in the specified DataBuffer from a primitive array of type TransferType.

**setDataElements(int, int, Object, DataBuffer)** - Method in class javax.media.jai.ComponentSampleModelJAI  
Sets the data for a single pixel in the specified DataBuffer from a primitive array of type TransferType.

**setDecodePaletteAsShorts(boolean)** - Method in class com.sun.media.jai.codec.TIFFDecodeParam  
If set, the entries in the palette will be decoded as shorts and no short to byte lookup will be applied to them.

**setDisplayExponent(float)** - Method in class com.sun.media.jai.codec.PNGDecodeParam  
Sets the display exponent to a given value.

**setElem(int, int)** - Method in class javax.media.jai.DataBufferDouble  
Sets the requested data array element in the first (default) bank to the given int.

**setElem(int, int)** - Method in class javax.media.jai.DataBufferFloat  
Sets the requested data array element in the first (default) bank to the given int.

**setElem(int, int, int)** - Method in class javax.media.jai.DataBufferDouble  
Sets the requested data array element in the specified bank to the given int.

**setElem(int, int, int)** - Method in class javax.media.jai.DataBufferFloat  
Sets the requested data array element in the specified bank to the given int.

**setElemDouble(int, double)** - Method in class javax.media.jai.DataBufferDouble  
Sets the requested data array element in the first (default) bank to the given double.

**setElemDouble(int, double)** - Method in class javax.media.jai.DataBufferFloat  
Sets the requested data array element in the first (default) bank to the given double.

**setElemDouble(int, int, double)** - Method in class javax.media.jai.DataBufferDouble  
Sets the requested data array element in the specified bank to the given double.

**setElemDouble(int, int, double)** - Method in class javax.media.jai.DataBufferFloat  
Sets the requested data array element in the specified bank to the given double.

**setElemFloat(int, float)** - Method in class javax.media.jai.DataBufferDouble  
Sets the requested data array element in the first (default) bank to the given float.

**setElemFloat(int, float)** - Method in class javax.media.jai.DataBufferFloat  
Sets the requested data array element in the first (default) bank to the given float.

**setElemFloat(int, int, float)** - Method in class javax.media.jai.DataBufferDouble  
Sets the requested data array element in the specified bank to the given float.

**setElemFloat(int, int, float)** - Method in class javax.media.jai.DataBufferFloat  
Sets the requested data array element in the specified bank to the given float.

**setEncodeParam(PNGEncodeParam)** - Method in class com.sun.media.jai.codec.PNGDecodeParam  
Sets the current encoder param instance.

**setExpandGrayAlpha(boolean)** - Method in class com.sun.media.jai.codec.PNGDecodeParam  
If set, images containing one channel of gray and one channel of alpha (GA) will be output in a 4-channel format (GGGA).

**setExpandPalette(boolean)** - Method in class com.sun.media.jai.codec.PNGDecodeParam  
If set, palette color images (PNG color type 3) will be decoded into full-color (RGB) output images.

**setFont(Font)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**setFont(Font)** - Method in class javax.media.jai.TiledImageGraphics

**setFont(Font)** - Method in class javax.media.jai.RenderableGraphics

**setGamma(float)** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Sets the file gamma value for the image.

**setGenerateEncodeParam(boolean)** - Method in class com.sun.media.jai.codec.PNGDecodeParam  
If set, an instance of PNGEncodeParam will be available after an image has been decoded via the getEncodeParam method that encapsulates information about the contents of the PNG file.

**setHeight(int)** - Method in class javax.media.jai.ImageLayout  
Sets height to the supplied value and marks it as valid.

**setHorizontalSubsampling(int, int)** - Method in class com.sun.media.jai.codec.JPEGEncodeParam  
Sets the horizontal subsampling to be applied to an image band.

**setICCProfileData(byte[])** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Sets the ICC profile data to be stored with this image.

**setImageParameters(ImageLayout, RenderedImage)** - Method in class javax.media.jai.PlanarImage  
Sets the image bounds, tile grid layout, SampleModel and ColorModel to match those of another image, overriding the image's values with values from an ImageLayout object.

**setImageParameters(RenderedImage)** - Method in class javax.media.jai.PlanarImage  
Sets the image bounds, tile grid layout, SampleModel and ColorModel to match those of another image.

**setInterlacing(boolean)** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Turns Adam7 interlacing on or off.

**setLumaQTable(int[])** - Method in class com.sun.media.jai.codec.JPEGEncodeParam  
Sets the quantization table to be used for luminance data.

**setMemoryCapacity(long)** - Method in interface javax.media.jai.TileCache  
Sets the memory capacity to a desired number of bytes.

**setMinX(int)** - Method in class javax.media.jai.ImageLayout  
Sets minX to the supplied value and marks it as valid.

**setMinY(int)** - Method in class javax.media.jai.ImageLayout  
Sets minY to the supplied value and marks it as valid.

**setModificationTime(Date)** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Sets the modification time, as a Date, to be stored with this image.

**setNext(Snapshot)** - Method in class javax.media.jai.Snapshot  
Sets the next Snapshot in the list to a given Snapshot.

**setNodeSource(Object, int)** - Method in class javax.media.jai.RenderedOp  
Sets the specified source stored in the ParameterBlock of this node to a new source object.

**setNumRetries(int)** - Method in class javax.media.jai.RemoteImage  
Set the number of retries.

**setOperationName(String)** - Method in class javax.media.jai.RenderedOp  
Sets the name of the operation this node represents.

**setOperationName(String)** - Method in class javax.media.jai.RenderableOp  
Sets the name of the operation this node represents.

**setOperationName(String)** - Method in class javax.media.jai.CollectionOp  
Sets the name of the operation this node represents.

**setOperationRegistry(OperationRegistry)** - Method in class javax.media.jai.JAI  
Sets the OperationRegistry to be used by this JAI instance.

**setOrigin(int, int)** - Method in class javax.media.jai.widget.ImageCanvas  
Changes the pixel to set Origin at x,y

**setOrigin(int, int)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Sets the image origin to a given (x, y) position.

**setOutput8BitGray(boolean)** - Method in class com.sun.media.jai.codec.PNGDecodeParam  
If set, grayscale images with a bit depth less than 8 (1, 2, or 4) will be output in 8 bit form.

**setPaint(Paint)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**setPaint(Paint)** - Method in class javax.media.jai.TiledImageGraphics

**setPaint(Paint)** - Method in class javax.media.jai.RenderableGraphics

**setPaintMode()** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**setPaintMode()** - Method in class javax.media.jai.TiledImageGraphics

**setPaintMode()** - Method in class javax.media.jai.RenderableGraphics

**setPalette(int[])** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Palette  
Sets the RGB palette of the image to be encoded.

**setPaletteHistogram(int[])** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Sets the palette histogram to be stored with this image.

**setPaletteTransparency(byte[])** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Palette  
Sets the alpha values associated with each palette entry.

**setParam(ImageDecodeParam)** - Method in class com.sun.media.jai.codec.ImageDecoderImpl  
Sets the current parameters to an instance of the ImageDecodeParam interface.

**setParam(ImageDecodeParam)** - Method in interface com.sun.media.jai.codec.ImageDecoder  
Sets the current parameters to an instance of the ImageDecodeParam interface.

**setParam(ImageEncodeParam)** - Method in class com.sun.media.jai.codec.ImageEncoderImpl  
Sets the current parameters to an instance of the ImageEncodeParam interface.

**setParam(ImageEncodeParam)** - Method in interface com.sun.media.jai.codec.ImageEncoder  
Sets the current parameters to an instance of the ImageEncodeParam interface.

**setParameter(byte, int)** - Method in class javax.media.jai.RenderedOp  
Sets one of the node's parameters to a byte.

**setParameter(byte, int)** - Method in class javax.media.jai.RenderableOp  
Sets one of the node's parameters to a byte.

**setParameter(char, int)** - Method in class javax.media.jai.RenderedOp  
Sets one of the node's parameters to a char.

**setParameter(char, int)** - Method in class javax.media.jai.RenderableOp  
Sets one of the node's parameters to a char.

**setParameter(double, int)** - Method in class javax.media.jai.RenderedOp  
Sets one of the node's parameters to a double.

**setParameter(double, int)** - Method in class javax.media.jai.RenderableOp  
Sets one of the node's parameters to a double.

**setParameter(float, int)** - Method in class javax.media.jai.RenderedOp  
Sets one of the node's parameters to a float.

**setParameter(float, int)** - Method in class javax.media.jai.RenderableOp  
Sets one of the node's parameters to a float.

**setParameter(int, int)** - Method in class javax.media.jai.RenderedOp  
Sets one of the node's parameters to an int.

**setParameter(int, int)** - Method in class javax.media.jai.RenderableOp  
Sets one of the node's parameters to an int.

**setParameter(long, int)** - Method in class javax.media.jai.RenderedOp  
Sets one of the node's parameters to a long.

**setParameter(long, int)** - Method in class javax.media.jai.RenderableOp  
Sets one of the node's parameters to a long.

**setParameter(Object, int)** - Method in class javax.media.jai.RenderedOp  
Sets one of the node's parameters to an Object.

**setParameter(Object, int)** - Method in class javax.media.jai.RenderableOp  
Sets one of the node's parameters to an Object.

**setParameter(short, int)** - Method in class javax.media.jai.RenderedOp  
Sets one of the node's parameters to a short.

**setParameter(short, int)** - Method in class javax.media.jai.RenderableOp  
Sets one of the node's parameters to a short.

**setParameterBlock(ParameterBlock)** - Method in class javax.media.jai.RenderedOp  
Sets the ParameterBlock of this node.

**setParameterBlock(ParameterBlock)** - Method in class javax.media.jai.RenderableOp  
Sets the ParameterBlock of this node.

**setParameterBlock(ParameterBlock)** - Method in class javax.media.jai.CollectionOp  
Sets the ParameterBlock of this node.

**setPerformGammaCorrection(boolean)** - Method in class com.sun.media.jai.codec.PNGDecodeParam  
Turns gamma corection of the image data on or off.

**setPhysicalDimension(int[])** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Sets the physical dimension information to be stored with this image.

**setPhysicalDimension(int, int, int)** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
A convenience method that calls the array version.

**setPixel(double[])** - Method in interface javax.media.jai.iterator.WritableRectIter  
Sets all samples of the current pixel to a set of double values.

**setPixel(float[])** - Method in interface javax.media.jai.iterator.WritableRectIter  
Sets all samples of the current pixel to a set of float values.

**setPixel(int[])** - Method in interface javax.media.jai.iterator.WritableRectIter  
Sets all samples of the current pixel to a set of int values.

**setPixel(int, int, double[])** - Method in interface javax.media.jai.iterator.WritableRandomIter  
Sets a pixel in the image using a float array of samples for input.

**setPixel(int, int, float[])** - Method in interface javax.media.jai.iterator.WritableRandomIter  
Sets a pixel in the image using a float array of samples for input.

**setPixel(int, int, int[])** - Method in interface javax.media.jai.iterator.WritableRandomIter  
Sets a pixel in the image using an int array of samples for input.

**setPreference(String, String)** - Method in class javax.media.jai.ProductOperationGraph  
Sets a preference between two products.

**setPrev(Snapshot)** - Method in class javax.media.jai.Snapshot  
Sets the previous Snapshot in the list to a given Snapshot.

**setProductPreference(String, String, String)** - Method in class javax.media.jai.OperationRegistry  
Sets a preference between two products registered under a common OperationDescriptor.

**setProductPreferenceNoLock(String, String, String)** - Method in class javax.media.jai.OperationRegistry

**setProperties(Hashtable)** - Method in class javax.media.jai.PlanarImage  
Sets the Hashtable containing the image properties to a given Hashtable.

**setProperties(Hashtable)** - Method in class javax.media.jai.NullOpImage  
Set the properties Hashtable of the source image to the supplied Hashtable.

**setProperty(String, Object)** - Method in class javax.media.jai.PlanarImage  
Sets a property on a PlanarImage.

**setProperty(String, Object)** - Method in class javax.media.jai.RenderedOp  
Sets a local property on a node.

**setProperty(String, Object)** - Method in class javax.media.jai.RenderableOp  
Sets a local property on a node.

**setProperty(String, Object)** - Method in class javax.media.jai.NullOpImage  
Sets a property on the source image by name.

**setQTable(int, int, int[])** - Method in class com.sun.media.jai.codec.JPEGEncodeParam  
Sets a quantization table to be used for a component.

**setQuality(float)** - Method in class com.sun.media.jai.codec.JPEGEncodeParam  
This creates new quantization tables that replace the currently installed quantization tables.

**setRaw(boolean)** - Method in class com.sun.media.jai.codec.PNMEncodeParam  
Sets the representation to be used.

**setRegistry(OperationRegistry)** - Method in class javax.media.jai.RenderedOp  
Sets the OperationRegistry that is used by this node.

**setRegistry(OperationRegistry)** - Method in class javax.media.jai.RenderableOp  
Sets the OperationRegistry that is used by this node.

**setRegistry(OperationRegistry)** - Method in class javax.media.jai.CollectionOp  
Sets the OperationRegistry that is used by this node.

**setRenderingHint(RenderingHints.Key, Object)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**setRenderingHint(RenderingHints.Key, Object)** - Method in class javax.media.jai.TiledImageGraphics

**setRenderingHint(RenderingHints.Key, Object)** - Method in class javax.media.jai.RenderableGraphics

**setRenderingHint(RenderingHints.Key, Object)** - Method in class javax.media.jai.JAI  
Sets the hint value associated with a given key in this JAI instance.

**setRenderingHints(Map)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**setRenderingHints(Map)** - Method in class javax.media.jai.TiledImageGraphics

**setRenderingHints(Map)** - Method in class javax.media.jai.RenderableGraphics

**setRenderingHints(RenderingHints)** - Method in class javax.media.jai.RenderedOp  
Sets the RenderingHints of this node.

**setRenderingHints(RenderingHints)** - Method in class javax.media.jai.JAI  
Sets the RenderingHints associated with this JAI instance.

**setRenderingHints(RenderingHints)** - Method in class javax.media.jai.CollectionOp  
Sets the RenderingHints of this node.

**setResolution(int)** - Method in class com.sun.media.jai.codec.FPXDecodeParam  
Sets the resolution to be decoded.

**setRestartInterval(int)** - Method in class com.sun.media.jai.codec.JPEGEncodeParam  
Sets the restart interval in Minimum Coded Units (MCUs).

**setRIFPreference(RenderedImageFactory, RenderedImageFactory)** - Method in class javax.media.jai.OperationGraph  
Sets a preference between two RIFs.

**setRIFPreference(String, String, RenderedImageFactory, RenderedImageFactory)** - Method in class javax.media.jai.OperationRegistry  
Sets a preference between two RIFs within the same product.

**setRIFPreferenceNoLock(String, String, RenderedImageFactory, RenderedImageFactory)** - Method in class `javax.media.jai.OperationRegistry`

**setRMIProperties(String)** - Method in class `javax.media.jai.RemoteImage`  
Cache the argument and the RMI ID as local properties.

**setSample(double)** - Method in interface `javax.media.jai.iterator.WritableRectIter`  
Sets the current sample to a double value.

**setSample(float)** - Method in interface `javax.media.jai.iterator.WritableRectIter`  
Sets the current sample to a float value.

**setSample(int)** - Method in interface `javax.media.jai.iterator.WritableRectIter`  
Sets the current sample to an integral value.

**setSample(int, double)** - Method in interface `javax.media.jai.iterator.WritableRectIter`  
Sets the specified sample of the current pixel to a double value.

**setSample(int, float)** - Method in interface `javax.media.jai.iterator.WritableRectIter`  
Sets the specified sample of the current pixel to a float value.

**setSample(int, int)** - Method in interface `javax.media.jai.iterator.WritableRectIter`  
Sets the specified sample of the current pixel to an integral value.

**setSample(int, int, int, double)** - Method in class `javax.media.jai.TiledImage`  
Sets a sample of a pixel to a given double value.

**setSample(int, int, int, double)** - Method in interface `javax.media.jai.iterator.WritableRandomIter`  
Sets the specified sample of the image to a double value.

**setSample(int, int, int, double, DataBuffer)** - Method in class `javax.media.jai.ComponentSampleModelJAI`  
Sets a sample in the specified band for the pixel located at (x,y) in the DataBuffer using a double for input.

**setSample(int, int, int, float)** - Method in class `javax.media.jai.TiledImage`  
Sets a sample of a pixel to a given float value.

**setSample(int, int, int, float)** - Method in interface `javax.media.jai.iterator.WritableRandomIter`  
Sets the specified sample of the image to a float value.

**setSample(int, int, int, float, DataBuffer)** - Method in class `javax.media.jai.ComponentSampleModelJAI`  
Sets a sample in the specified band for the pixel located at (x,y) in the DataBuffer using a float for input.

**setSample(int, int, int, int)** - Method in class `javax.media.jai.TiledImage`  
Sets a sample of a pixel to a given value.

**setSample(int, int, int, int)** - Method in interface `javax.media.jai.iterator.WritableRandomIter`  
Sets the specified sample of the image to an integral value.

**setSampleModel(SampleModel)** - Method in class `javax.media.jai.ImageLayout`  
Sets sampleModel to the supplied value and marks it as valid.

**setSegmentLength(int)** - Method in class `com.sun.media.jai.codec.StreamSegment`  
Sets the length of the segment.

**setSignificantBits(int[])** - Method in class `com.sun.media.jai.codec.PNGEncodeParam`  
Sets the number of significant bits for each band of the image.

**setSource(Object, int)** - Method in class `javax.media.jai.RenderableOp`  
Sets one of the node's sources to an Object.

**setSource(PlanarImage, int)** - Method in class `javax.media.jai.PlanarImage`  
Helper for `RenderedOp.setSource()`.

**setSource(PlanarImage, int)** - Method in class `javax.media.jai.RenderedOp`  
Renders the node if it has not already been rendered, and sets the specified source of the rendered image to the supplied `PlanarImage`.

**setSources(List)** - Method in class `javax.media.jai.PlanarImage`  
Set the list of sources from a given List of `PlanarImages`.

**setSources(List)** - Method in class `javax.media.jai.RenderedOp`  
Replaces the sources in the `ParameterBlock` of this node with a new list of sources.

**setSRGBIntent(int)** - Method in class `com.sun.media.jai.codec.PNGEncodeParam`  
Sets the sRGB rendering intent to be stored with this image.

**setStartPos(long)** - Method in class `com.sun.media.jai.codec.StreamSegment`  
Sets the starting position of the segment.

**setStroke(Stroke)** - Method in class `javax.media.jai.GraphicsJAI`  
See comments in `java.awt.Graphics2D`.

**setStroke(Stroke)** - Method in class `javax.media.jai.TiledImageGraphics`

**setStroke(Stroke)** - Method in class `javax.media.jai.RenderableGraphics`

**setSuggestedPalette(PNGSuggestedPaletteEntry[])** - Method in class `com.sun.media.jai.codec.PNGEncodeParam`  
Sets the suggested palette information to be stored with this image.

**setSuppressAlpha(boolean)** - Method in class `com.sun.media.jai.codec.PNGDecodeParam`  
If set, no alpha (transparency) channel will appear in the output image.

**setTail(Snapshot)** - Method in class `javax.media.jai.SnapshotImage`  
Sets the reference to the most current Snapshot to a given Snapshot.

**setText(String[])** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Sets the textual data to be stored in uncompressed form with this image.

**setThreshold(int)** - Method in class javax.media.jai.ROI  
Sets the inclusion/exclusion threshold value.

**setTileCache(TileCache)** - Method in class javax.media.jai.OpImage  
Sets the tile cache of this image.

**setTileCache(TileCache)** - Method in class javax.media.jai.JAI  
Sets the TileCache to be used by this JAI instance.

**setTileCapacity(int)** - Method in interface javax.media.jai.TileCache  
Sets the tile capacity to a desired number of tiles.

**setTileGridXOffset(int)** - Method in class javax.media.jai.ImageLayout  
Sets tileGridXOffset to the supplied value and marks it as valid.

**setTileGridYOffset(int)** - Method in class javax.media.jai.ImageLayout  
Sets tileGridYOffset to the supplied value and marks it as valid.

**setTileHeight(int)** - Method in class javax.media.jai.ImageLayout  
Sets tileHeight to the supplied value and marks it as valid.

**setTileScheduler(TileScheduler)** - Method in class javax.media.jai.JAI  
Sets the TileScheduler to be used by this JAI instance.

**setTileWidth(int)** - Method in class javax.media.jai.ImageLayout  
Sets tileWidth to the supplied value and marks it as valid.

**setTimeout(int)** - Method in class javax.media.jai.RemoteImage  
Set the amount of time between retries.

**setToIdentity()** - Method in class javax.media.jai.PerspectiveTransform  
Resets this transform to the Identity transform.

**setTopDown(boolean)** - Method in class com.sun.media.jai.codec.BMPEncodeParam  
If set, the data will be written out in a top-down manner, the first scanline being written first.

**setToRotation(double)** - Method in class javax.media.jai.PerspectiveTransform  
Sets this transform to a rotation transformation.

**setToRotation(double, double, double)** - Method in class javax.media.jai.PerspectiveTransform  
Sets this transform to a rotation transformation about a specified point (x, y).

**setToScale(double, double)** - Method in class javax.media.jai.PerspectiveTransform  
Sets this transform to a scale transformation with scale factors sx and sy.

**setToShear(double, double)** - Method in class javax.media.jai.PerspectiveTransform  
Sets this transform to a shearing transformation with shear factors sx and sy.

**setToTranslation(double, double)** - Method in class javax.media.jai.PerspectiveTransform  
Sets this transform to a translation transformation.

**setTransform(AffineTransform)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**setTransform(AffineTransform)** - Method in class javax.media.jai.PerspectiveTransform  
Sets this transform to a given AffineTransform.

**setTransform(AffineTransform)** - Method in class javax.media.jai.TiledImageGraphics

**setTransform(AffineTransform)** - Method in class javax.media.jai.RenderableGraphics

**setTransform(float, float, float, float, float, float, float, float, float, float)** - Method in class javax.media.jai.PerspectiveTransform  
Sets this transform to a given PerspectiveTransform, expressed by the elements of its matrix.

**setTransform(PerspectiveTransform)** - Method in class javax.media.jai.PerspectiveTransform  
Sets this transform to a given PerspectiveTransform.

**setTransparentGray(int)** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Gray  
Sets the gray value to be used to denote transparency.

**setTransparentRGB(int[])** - Method in class com.sun.media.jai.codec.PNGEncodeParam.RGB  
Sets the RGB value to be used to denote transparency.

**setUserExponent(float)** - Method in class com.sun.media.jai.codec.PNGDecodeParam  
Sets the user exponent to a given value.

**setValid(int)** - Method in class javax.media.jai.ImageLayout  
Sets selected bits of the valid bitmask.

**setVersion(int)** - Method in class com.sun.media.jai.codec.BMPEncodeParam  
Sets the BMP version to be used.

**setVerticalSubsampling(int, int)** - Method in class com.sun.media.jai.codec.JPEGEncodeParam  
Sets the vertical subsampling to be applied to an image band.

**setViewport(int, int, int, int)** - Method in interface javax.media.jai.widget.ViewportListener  
Called to inform the listener of the currently viewable area of the source image.

**setWidth(int)** - Method in class javax.media.jai.ImageLayout  
Sets width to the supplied value and marks it as valid.

**setWriteImageOnly(boolean)** - Method in class com.sun.media.jai.codec.JPEGEncodeParam  
Controls whether the encoder writes only the compressed image data to the output stream.

**setWriteJFIFHeader(boolean)** - Method in class com.sun.media.jai.codec.JPEGEncodeParam  
Controls whether the encoder writes a JFIF header using the APP0 marker.

**setWriteTablesOnly(boolean)** - Method in class com.sun.media.jai.codec.JPEGEncodeParam  
Instructs the encoder to write only the table data to the output stream.

**setWriteTiled(boolean)** - Method in class com.sun.media.jai.codec.TIFFEncodeParam  
If set, the data will be written out in tiled format, instead of in strips.

**setXORMode(Color)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics.

**setXORMode(Color)** - Method in class javax.media.jai.TiledImageGraphics

**setXORMode(Color)** - Method in class javax.media.jai.RenderableGraphics

**setZeroLink(PartialOrderNode)** - Method in class javax.media.jai.PartialOrderNode  
Sets the next zero in-degree node in the linked list.

**sgn(int)** - Method in class javax.media.jai.ROIShape.PolyShape  
Calculate the sign of the argument.

**SHEAR\_HORIZONTAL** - Static variable in class javax.media.jai.operator.ShearDescriptor

**SHEAR\_VERTICAL** - Static variable in class javax.media.jai.operator.ShearDescriptor

**shear(double, double)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**shear(double, double)** - Method in class javax.media.jai.PerspectiveTransform  
Concatenates this transform with a shearing transformation.

**shear(double, double)** - Method in class javax.media.jai.TiledImageGraphics

**shear(double, double)** - Method in class javax.media.jai.RenderableGraphics

**ShearDescriptor** - class javax.media.jai.operator.ShearDescriptor.  
An `OperationDescriptor` describing the "Shear" operation.

**ShearDescriptor()** - Constructor for class javax.media.jai.operator.ShearDescriptor  
Constructor.

**ShearPropertyGenerator** - class javax.media.jai.operator.ShearPropertyGenerator.  
This property generator computes the properties for the operation "Shear" dynamically.

**ShearPropertyGenerator()** - Constructor for class javax.media.jai.operator.ShearPropertyGenerator  
Constructor.

**shift** - Variable in class javax.media.jai.InterpolationBilinear

**shift2** - Variable in class javax.media.jai.InterpolationBilinear

**shortDataArrays** - Variable in class javax.media.jai.RasterAccessor  
The image data in a two-dimensional short array.

**significantBits** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**significantBitsSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**sinks** - Variable in class javax.media.jai.PlanarImage  
A set of `WeakReferences` to the image's sinks.

**size()** - Method in class javax.media.jai.CollectionImage  
Returns the number of elements in this collection.

**size()** - Method in class javax.media.jai.CollectionOp  
Returns the number of elements in this collection.

**sizeOfType** - Static variable in class com.sun.media.jai.codec.TIFFDirectory

**skip(int)** - Method in class com.sun.media.jai.codec.FileSeekableStream

**skip(long)** - Method in class com.sun.media.jai.codec.ForwardSeekableStream  
Forwards the request to the real `InputStream`.

**skipBytes(int)** - Method in class com.sun.media.jai.codec.SeekableStream  
Attempts to skip over n bytes of input discarding the skipped bytes.

**skipBytes(int)** - Method in class com.sun.media.jai.codec.ByteArraySeekableStream  
Attempts to skip over n bytes of input discarding the skipped bytes.

**snapshot** - Variable in class javax.media.jai.PlanarImage  
A `SnapshotImage` that will centralize tile versioning for this image.

**Snapshot** - class javax.media.jai.Snapshot.  
A non-public class that holds a portion of the state associated with a `SnapshotImage`.

**Snapshot(SnapshotImage)** - Constructor for class javax.media.jai.Snapshot  
Constructs a Snapshot that will provide a synchronous view of a SnapshotImage at a particular moment in time.

**SnapshotImage** - class javax.media.jai.SnapshotImage.  
A class providing an arbitrary number of synchronous views of a possibly changing WritableRenderedImage.

**SnapshotImage(PlanarImage)** - Constructor for class javax.media.jai.SnapshotImage  
Constructs a SnapshotImage from a PlanarImage source.

**SnapshotProxy** - class javax.media.jai.SnapshotProxy.  
A proxy for Snapshot that calls Snapshot.dispose() when finalized.

**SnapshotProxy(Snapshot)** - Constructor for class javax.media.jai.SnapshotProxy  
Construct a new proxy for a given Snapshot.

**source** - Variable in class javax.media.jai.SnapshotImage  
The real image source.

**source0** - Variable in class javax.media.jai.PlanarImage  
The image's first source, stored separately for convenience.

**source0AsOpImage** - Variable in class javax.media.jai.PointOpImage

**source0AsWritableRenderedImage** - Variable in class javax.media.jai.PointOpImage

**source0IsWritableRenderedImage** - Variable in class javax.media.jai.PointOpImage

**source1** - Variable in class javax.media.jai.PlanarImage  
The image's second source, stored separately for convenience.

**sourceClasses** - Variable in class javax.media.jai.OperationDescriptorImpl  
An array of Classes that describe the types of sources required by this operation in the rendered mode.

**sourceClasses** - Static variable in class javax.media.jai.operator.AddConstToCollectionDescriptor  
The source class list for this operation.

**sourceClasses** - Static variable in class javax.media.jai.operator.AddCollectionDescriptor  
The source class list for this operation.

**sourceForProp** - Variable in class javax.media.jai.OperationRegistry

**sourceForProp** - Variable in class javax.media.jai.PropertySourceImpl

**sourceIndex** - Variable in class javax.media.jai.PropertyGeneratorFromSource

**SourcelessOpImage** - class javax.media.jai.SourcelessOpImage.  
An abstract base class for image operators that have no image sources.

**SourcelessOpImage(int, int, int, int, SampleModel, TileCache, ImageLayout)** - Constructor for class javax.media.jai.SourcelessOpImage  
Constructs a SourcelessOpImage.

**sources** - Variable in class javax.media.jai.PlanarImage  
The image's third and later sources, stored in a Vector.

**sources** - Variable in class javax.media.jai.PropertySourceImpl

**src** - Variable in class javax.media.jai.TiledImage  
The source image for uncomputed tiles.

**src** - Variable in class com.sun.media.jai.codec.ForwardSeekableStream  
The source InputStream.

**src** - Variable in class com.sun.media.jai.codec.ByteArraySeekableStream  
Array holding the source data.

**src** - Variable in class com.sun.media.jai.codec.MemoryCacheSeekableStream  
The source input stream.

**srcROI** - Variable in class javax.media.jai.TiledImage

**SRGBIntent** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**SRGBIntentSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**startBands()** - Method in interface javax.media.jai.iterator.RectIter  
Sets the iterator to the first band of the image.

**startDrag(Point)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Called at the beginning of a mouse drag.

**startEnumeration()** - Method in class javax.media.jai.IntegerSequence  
Resets the iterator to the beginning of the sequence.

**startLines()** - Method in interface javax.media.jai.iterator.RectIter  
Sets the iterator to the first line of its bounding rectangle.

**startPixels()** - Method in interface javax.media.jai.iterator.RectIter  
Sets the iterator to the leftmost pixel of its bounding rectangle.

**startPos** - Variable in class com.sun.media.jai.codec.StreamSegment

**startPosition(int, int, int)** - Method in class javax.media.jai.Histogram

**StatisticsOpImage** - class javax.media.jai.StatisticsOpImage.

An abstract base class for image operators that compute statistics on a given region of an image, and with a given sampling rate.

**StatisticsOpImage(RenderedImage, ROI, int, int, int, int, int, int)** - Constructor for class javax.media.jai.StatisticsOpImage

Constructs a StatisticsOpImage.

**Storage** - class javax.media.jai.Storage.

**Storage(String, String, String, String)** - Constructor for class javax.media.jai.Storage

**Store** - class javax.media.jai.Store.

**Store(String, Object, Object)** - Constructor for class javax.media.jai.Store

**stream** - Variable in class com.sun.media.jai.codec.SegmentedSeekableStream

**stream** - Variable in class com.sun.media.jai.codec.FileCacheSeekableStream

The source stream.

**stream** - Variable in class com.sun.media.jai.codec.TIFFDirectory

The stream being read.

**StreamDescriptor** - class javax.media.jai.operator.StreamDescriptor.

An OperationDescriptor describing the "Stream" operation.

**StreamDescriptor()** - Constructor for class javax.media.jai.operator.StreamDescriptor

Constructor.

**streamSegment** - Variable in class com.sun.media.jai.codec.SegmentedSeekableStream

**StreamSegment** - class com.sun.media.jai.codec.StreamSegment.

A utility class representing a segment within a stream as a long starting position and an int length.

**StreamSegment()** - Constructor for class com.sun.media.jai.codec.StreamSegment

Constructs a StreamSegment.

**StreamSegment(long, int)** - Constructor for class com.sun.media.jai.codec.StreamSegment

Constructs a StreamSegment with a given starting position and length.

**StreamSegmentMapper** - interface com.sun.media.jai.codec.StreamSegmentMapper.

An interface for use with the SegmentedSeekableStream class.

**StreamSegmentMapperImpl** - class com.sun.media.jai.codec.StreamSegmentMapperImpl.

An implementation of the StreamSegmentMapper interface that requires an explicit list of the starting locations and lengths of the source segments.

**StreamSegmentMapperImpl(long[], int[])** - Constructor for class com.sun.media.jai.codec.StreamSegmentMapperImpl

**stroke** - Variable in class javax.media.jai.TiledImageGraphics

**stroke** - Variable in class javax.media.jai.RenderableGraphics

**subsampleBitsH** - Variable in class javax.media.jai.Interpolation

The numbers of bits used for the horizontal subsample position.

**subsampleBitsV** - Variable in class javax.media.jai.Interpolation

The numbers of bits used for the vertical subsample position.

**subtract(ROI)** - Method in class javax.media.jai.ROI

Subtracts another ROI from this one and returns the result as a new ROI.

**subtract(ROI)** - Method in class javax.media.jai.ROIShape

Subtracts another mask from this one.

**SubtractConstDescriptor** - class javax.media.jai.operator.SubtractConstDescriptor.

An OperationDescriptor describing the "SubtractConst" operation.

**SubtractConstDescriptor()** - Constructor for class javax.media.jai.operator.SubtractConstDescriptor

Constructor.

**SubtractDescriptor** - class javax.media.jai.operator.SubtractDescriptor.

An OperationDescriptor describing the "Subtract" operation.

**SubtractDescriptor()** - Constructor for class javax.media.jai.operator.SubtractDescriptor

Constructor.

**SubtractFromConstDescriptor** - class javax.media.jai.operator.SubtractFromConstDescriptor.

An OperationDescriptor describing the "SubtractFromConst" operation.

**SubtractFromConstDescriptor()** - Constructor for class javax.media.jai.operator.SubtractFromConstDescriptor

Constructor.

**suggestedPalette** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**suggestedPaletteSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**suppNames** - Variable in class javax.media.jai.PropertySourceImpl

**suppressAllProperties(String)** - Method in class javax.media.jai.OperationRegistry  
Forces all properties to be suppressed by nodes performing a particular operation.

**suppressAlpha** - Variable in class com.sun.media.jai.codec.PNGDecodeParam

**suppressed** - Variable in class javax.media.jai.OperationRegistry

**suppressProperty(String)** - Method in class javax.media.jai.RenderedOp  
Removes a named property from the property environment of this node.

**suppressProperty(String)** - Method in class javax.media.jai.RenderableOp  
Removes a named property from the property environment of this node.

**suppressProperty(String)** - Method in class javax.media.jai.PropertySourceImpl

**suppressProperty(String, String)** - Method in class javax.media.jai.OperationRegistry  
Forces a particular property to be suppressed by nodes performing a particular operation.

**synthProperties** - Variable in class javax.media.jai.RenderedOp  
Synthesized properties.

**synthProps** - Static variable in class javax.media.jai.RenderedOp  
Names of synthesized properties.

---

## T

**tag** - Variable in class com.sun.media.jai.codec.TIFFField  
The tag number.

**TAG\_BYTE\_EXPANDED** - Static variable in class javax.media.jai.RasterAccessor  
FormatTagID indicating data in byte arrays and uncopied.

**TAG\_BYTE\_UNCOPIED** - Static variable in class javax.media.jai.RasterAccessor  
FormatTagID indicating data in byte arrays and uncopied.

**TAG\_DOUBLE\_COPIED** - Static variable in class javax.media.jai.RasterAccessor  
FormatTagID indicating data in double arrays and copied.

**TAG\_DOUBLE\_UNCOPIED** - Static variable in class javax.media.jai.RasterAccessor  
FormatTagID indicating data in double arrays and uncopied.

**TAG\_FLOAT\_COPIED** - Static variable in class javax.media.jai.RasterAccessor  
FormatTagID indicating data in float arrays and copied.

**TAG\_FLOAT\_UNCOPIED** - Static variable in class javax.media.jai.RasterAccessor  
FormatTagID indicating data in float arrays and uncopied.

**TAG\_INT\_COPIED** - Static variable in class javax.media.jai.RasterAccessor  
FormatTagID indicating data in int arrays and copied.

**TAG\_INT\_UNCOPIED** - Static variable in class javax.media.jai.RasterAccessor  
FormatTagID indicating data in int arrays and uncopied.

**TAG\_SHORT\_UNCOPIED** - Static variable in class javax.media.jai.RasterAccessor  
FormatTagID indicating data in short arrays and uncopied.

**TAG\_USHORT\_UNCOPIED** - Static variable in class javax.media.jai.RasterAccessor  
FormatTagID indicating data in unsigned short arrays and uncopied.

**tail** - Variable in class javax.media.jai.SnapshotImage  
The last entry in the list of Snapshots, initially null.

**text** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**textSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**theDest** - Variable in class javax.media.jai.AreaOpImage

**theImage** - Variable in class javax.media.jai.RenderedOp  
The rendering of the current image, not preserved over RMI.

**theImage** - Variable in class javax.media.jai.ROI  
The PlanarImage representation of the ROI.

**theImage** - Variable in class javax.media.jai.RenderedImageAdapter  
The RenderedImage being adapted.

**theImage** - Variable in class javax.media.jai.WritableRenderedImageAdapter  
The WritableRenderedImage being adapted.

**thePropertySource** - Variable in class javax.media.jai.RenderedOp  
The PropertySource containing the combined properties of all of the node's sources.

**thePropertySource** - Variable in class javax.media.jai.RenderableOp

**theRegistry** - Variable in class javax.media.jai.RenderedOp  
The OperationRegistry that is used to render this node.

**theRegistry** - Variable in class javax.media.jai.RenderableOp  
The OperationRegistry that is used to render this node.

**theShape** - Variable in class javax.media.jai.ROIShape  
The internal Shape that defines this mask.

**threshold** - Variable in class javax.media.jai.ROI  
The inclusion/exclusion threshold of the ROI.

**ThresholdDescriptor** - class javax.media.jai.operator.ThresholdDescriptor.  
An OperationDescriptor describing the "Threshold" operation.

**ThresholdDescriptor()** - Constructor for class javax.media.jai.operator.ThresholdDescriptor  
Constructor.

**TIFF\_ASCII** - Static variable in class com.sun.media.jai.codec.TIFFField  
Flag for null-terminated ASCII strings.

**TIFF\_BYTE** - Static variable in class com.sun.media.jai.codec.TIFFField  
Flag for 8 bit unsigned integers.

**TIFF\_DOUBLE** - Static variable in class com.sun.media.jai.codec.TIFFField  
Flag for 64 bit IEEE doubles.

**TIFF\_FLOAT** - Static variable in class com.sun.media.jai.codec.TIFFField  
Flag for 32 bit IEEE floats.

**TIFF\_LONG** - Static variable in class com.sun.media.jai.codec.TIFFField  
Flag for 32 bit unsigned integers.

**TIFF\_RATIONAL** - Static variable in class com.sun.media.jai.codec.TIFFField  
Flag for pairs of 32 bit unsigned integers.

**TIFF\_SBYTE** - Static variable in class com.sun.media.jai.codec.TIFFField  
Flag for 8 bit signed integers.

**TIFF\_SHORT** - Static variable in class com.sun.media.jai.codec.TIFFField  
Flag for 16 bit unsigned integers.

**TIFF\_SLONG** - Static variable in class com.sun.media.jai.codec.TIFFField  
Flag for 32 bit signed integers.

**TIFF\_SRATIONAL** - Static variable in class com.sun.media.jai.codec.TIFFField  
Flag for pairs of 32 bit signed integers.

**TIFF\_SSHORT** - Static variable in class com.sun.media.jai.codec.TIFFField  
Flag for 16 bit signed integers.

**TIFF\_UNDEFINED** - Static variable in class com.sun.media.jai.codec.TIFFField  
Flag for 8 bit uninterpreted bytes.

**TIFFDecodeParam** - class com.sun.media.jai.codec.TIFFDecodeParam.  
An instance of ImageDecodeParam for decoding images in the TIFF format.

**TIFFDecodeParam()** - Constructor for class com.sun.media.jai.codec.TIFFDecodeParam  
Constructs a default instance of TIFFDecodeParam.

**TIFFDescriptor** - class javax.media.jai.operator.TIFFDescriptor.  
An OperationDescriptor describing the "TIFF" operation.

**TIFFDescriptor()** - Constructor for class javax.media.jai.operator.TIFFDescriptor  
Constructor.

**TIFFDirectory** - class com.sun.media.jai.codec.TIFFDirectory.  
A class representing an Image File Directory (IFD) from a TIFF 6.0 stream.

**TIFFDirectory()** - Constructor for class com.sun.media.jai.codec.TIFFDirectory  
The default constructor.

**TIFFDirectory(SeekableStream, int)** - Constructor for class com.sun.media.jai.codec.TIFFDirectory  
Constructs a TIFFDirectory from a SeekableStream.

**TIFFDirectory(SeekableStream, long)** - Constructor for class com.sun.media.jai.codec.TIFFDirectory  
Constructs a TIFFDirectory by reading a SeekableStream.

**TIFFEncodeParam** - class com.sun.media.jai.codec.TIFFEncodeParam.  
An instance of ImageEncodeParam for encoding images in the TIFF format.

**TIFFEncodeParam()** - Constructor for class com.sun.media.jai.codec.TIFFEncodeParam  
Constructs a TIFFEncodeParam object with default values for parameters.

**TIFFField** - class com.sun.media.jai.codec.TIFFField.  
A class representing a field in a TIFF 6.0 Image File Directory.

**TIFFField()** - Constructor for class com.sun.media.jai.codec.TIFFField  
The default constructor.

**TIFFField(int, int, int, Object)** - Constructor for class com.sun.media.jai.codec.TIFFField  
Constructs a TIFFField with arbitrary data.

**tile** - Variable in class javax.media.jai.TileCopy  
The tile's Raster data.

**TILE\_GRID\_X\_OFFSET\_MASK** - Static variable in class javax.media.jai.ImageLayout  
A bitmask to specify the validity of tileGridXOffset.

**TILE\_GRID\_Y\_OFFSET\_MASK** - Static variable in class javax.media.jai.ImageLayout  
A bitmask to specify the validity of tileGridYOffset.

**TILE\_HEIGHT\_MASK** - Static variable in class javax.media.jai.ImageLayout  
A bitmask to specify the validity of tileHeight.

**TILE\_WIDTH\_MASK** - Static variable in class javax.media.jai.ImageLayout  
A bitmask to specify the validity of tileWidth.

**tileCache** - Variable in class javax.media.jai.JAI

**TileCache** - interface javax.media.jai.TileCache.  
A class implementing a caching mechanism for image tiles.

**TileCopy** - class javax.media.jai.TileCopy.  
A (Raster, X, Y) tuple.

**TileCopy(Raster, int, int)** - Constructor for class javax.media.jai.TileCopy  
Constructs a TileCopy object given the tile's Raster data and its location in the tile grid.

**tileDependencies** - Variable in class javax.media.jai.UntiledOpImage  
The tile dependency array: needs to be computed only once.

**tiledImage** - Variable in class javax.media.jai.TiledImageGraphics

**TiledImage** - class javax.media.jai.TiledImage.  
A concrete implementation of WritableRenderedImage.

**TiledImage(int, int, int, int, int, int, SampleModel, ColorModel)** - Constructor for class javax.media.jai.TiledImage  
Constructs a TiledImage with a given layout, SampleModel, and ColorModel.

**TiledImage(Point, SampleModel, int, int)** - Constructor for class javax.media.jai.TiledImage  
Constructs a TiledImage with a SampleModel that is compatible with a given SampleModel, and given tile dimensions.

**TiledImage(SampleModel, int, int)** - Constructor for class javax.media.jai.TiledImage  
Constructs a TiledImage starting at the global coordinate origin.

**TiledImage(TiledImage, int, int, int, int, int, int, SampleModel, ColorModel)** - Constructor for class javax.media.jai.TiledImage

**TiledImageGraphics** - class javax.media.jai.TiledImageGraphics.  
A concrete (i.e., non-abstract) class implementing all the methods of Graphics2D (and thus of Graphics) with a TiledImage as the implicit drawing canvas.

**TiledImageGraphics(TiledImage)** - Constructor for class javax.media.jai.TiledImageGraphics  
Construct a TiledImageGraphics object that draws onto a particular TiledImage.

**tileGridXOffset** - Variable in class javax.media.jai.ImageLayout  
The X coordinate of tile (0, 0).

**tileGridXOffset** - Variable in class javax.media.jai.PlanarImage  
The X coordinate of the upper-left pixel of tile (0, 0).

**tileGridXOffset** - Variable in class javax.media.jai.widget.ImageCanvas  
The image's tile grid X offset.

**tileGridYOffset** - Variable in class javax.media.jai.ImageLayout  
The Y coordinate of tile (0, 0).

**tileGridYOffset** - Variable in class javax.media.jai.PlanarImage  
The Y coordinate of the upper-left pixel of tile (0, 0).

**tileGridYOffset** - Variable in class javax.media.jai.widget.ImageCanvas  
The image's tile grid Y offset.

**tileHeight** - Variable in class javax.media.jai.ImageLayout  
The height of a tile.

**tileHeight** - Variable in class javax.media.jai.PlanarImage  
The height of a tile.

**tileHeight** - Variable in class javax.media.jai.TiledImageGraphics

**tileHeight** - Variable in class javax.media.jai.widget.ImageCanvas  
The image's tile height.

**tileIntersectsROI(int, int)** - Method in class javax.media.jai.StatisticsOpImage

**tileObservers** - Variable in class javax.media.jai.TiledImage  
The current set of TileObservers.

**tiles** - Variable in class javax.media.jai.Snapshot  
A set of cached TileCopy elements.

**tiles** - Variable in class javax.media.jai.TiledImage  
The tile array.

**tileScheduler** - Variable in class javax.media.jai.JAI

**TileScheduler** - interface javax.media.jai.TileScheduler.

A class implementing a mechanism for scheduling tile calculation.

**tilesX** - Variable in class javax.media.jai.TiledImage

The number of tiles in the X direction.

**tilesY** - Variable in class javax.media.jai.TiledImage

The number of tiles in the Y direction.

**tileUpdate(WritableRenderedImage, int, int, boolean)** - Method in class javax.media.jai.SnapshotImage

Receives the information that a tile is either about to become writable, or is about to become no longer writable.

**tileWidth** - Variable in class javax.media.jai.ImageLayout

The width of a tile.

**tileWidth** - Variable in class javax.media.jai.PlanarImage

The width of a tile.

**tileWidth** - Variable in class javax.media.jai.TiledImageGraphics

**tileWidth** - Variable in class javax.media.jai.widget.ImageCanvas

The image's tile width.

**tileX** - Variable in class javax.media.jai.TileCopy

The tile's column within the image tile grid.

**tileXMaximum** - Variable in class javax.media.jai.TiledImageGraphics

**tileXMinimum** - Variable in class javax.media.jai.TiledImageGraphics

**tileXToX(int)** - Method in class javax.media.jai.PlanarImage

Converts a horizontal tile index into the X coordinate of its upper left pixel.

**TileXtoX(int)** - Method in class javax.media.jai.widget.ImageCanvas

**tileXToX(int, int, int)** - Static method in class javax.media.jai.PlanarImage

Converts a horizontal tile index into the X coordinate of its upper left pixel relative to a given tile grid layout specified by its X offset and tile width.

**tileY** - Variable in class javax.media.jai.TileCopy

The tile's row within the image tile grid.

**tileYMaximum** - Variable in class javax.media.jai.TiledImageGraphics

**tileYMinimum** - Variable in class javax.media.jai.TiledImageGraphics

**tileYToY(int)** - Method in class javax.media.jai.PlanarImage

Converts a vertical tile index into the Y coordinate of its upper left pixel.

**TileYtoY(int)** - Method in class javax.media.jai.widget.ImageCanvas

**tileYToY(int, int, int)** - Static method in class javax.media.jai.PlanarImage

Converts a vertical tile index into the Y coordinate of its upper left pixel relative to a given tile grid layout specified by its Y offset and tile height.

**timeout** - Variable in class javax.media.jai.RemoteImage

The amount of time between retries (milliseconds).

**timeStamp** - Variable in class javax.media.jai.SequentialImage

The time stamp associated with the image.

**toArray()** - Method in class javax.media.jai.CollectionImage

Returns an array containing all of the elements in this collection.

**toArray()** - Method in class javax.media.jai.CollectionOp

Returns an array containing all of the elements in this collection.

**toArray(Object[])** - Method in class javax.media.jai.CollectionImage

Returns an array containing all of the elements in this collection whose runtime type is that of the specified array.

**toArray(Object[])** - Method in class javax.media.jai.CollectionOp

Returns an array containing all of the elements in this collection whose runtime type is that of the specified array.

**toFloatArray(double[])** - Method in class javax.media.jai.RasterAccessor

**toIntArray(double[])** - Method in class javax.media.jai.RasterAccessor

**topDown** - Variable in class com.sun.media.jai.codec.BMPEncodeParam

**topPadding** - Variable in class javax.media.jai.Interpolation

The number of pixels lying above the interpolation kernel key position.

**topPadding** - Variable in class javax.media.jai.AreaOpImage

The number of source pixels needed above the central pixel.

**toString()** - Method in class javax.media.jai.ImageLayout  
Returns a String containing the values of all valid fields.

**toString()** - Method in class javax.media.jai.FloatDoubleColorModel  
Returns a String containing the values of all valid fields.

**toString()** - Method in class javax.media.jai.ComponentSampleModelJAI  
Returns a String containing the values of all valid fields.

**toString()** - Method in class javax.media.jai.PerspectiveTransform  
Returns a String that represents the value of this Object.

**toString()** - Method in class javax.media.jai.OperationRegistry  
Returns a String representation of the registry.

**toString()** - Method in class javax.media.jai.IntegerSequence  
Returns a String representation of the sequence for debugging.

**totalLength** - Variable in class com.sun.media.jai.codec.SectorStreamSegmentMapper

**tpad** - Variable in class javax.media.jai.ScaleOpImage

**transform** - Variable in class javax.media.jai.WarpAffine

**transform** - Variable in class javax.media.jai.WarpPerspective

**transform** - Variable in class javax.media.jai.TiledImageGraphics

**transform** - Variable in class javax.media.jai.RenderableGraphics

**transform(AffineTransform)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**transform(AffineTransform)** - Method in class javax.media.jai.ROI  
Performs an affine transformation and returns the result as a new ROI.

**transform(AffineTransform)** - Method in class javax.media.jai.TiledImageGraphics

**transform(AffineTransform)** - Method in class javax.media.jai.RenderableGraphics

**transform(AffineTransform)** - Method in class javax.media.jai.ROIShape  
Transforms the current contents of the ROI by a given AffineTransform.

**transform(AffineTransform, Interpolation)** - Method in class javax.media.jai.ROI  
Performs an affine transformation and returns the result as a new ROI.

**transform(double[], int, double[], int, int)** - Method in class javax.media.jai.PerspectiveTransform  
Transforms an array of double precision coordinates by this transform.

**transform(double[], int, float[], int, int)** - Method in class javax.media.jai.PerspectiveTransform  
Transforms an array of double precision coordinates by this transform, storing the results into an array of floats.

**transform(float[], int, double[], int, int)** - Method in class javax.media.jai.PerspectiveTransform  
Transforms an array of floating point coordinates by this transform, storing the results into an array of doubles.

**transform(float[], int, float[], int, int)** - Method in class javax.media.jai.PerspectiveTransform  
Transforms an array of floating point coordinates by this transform.

**transform(Point2D[], int, Point2D[], int, int)** - Method in class javax.media.jai.PerspectiveTransform  
Transforms an array of point objects by this transform.

**transform(Point2D, Point2D)** - Method in class javax.media.jai.PerspectiveTransform  
Transforms the specified ptSrc and stores the result in ptDst.

**translate(double, double)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**translate(double, double)** - Method in class javax.media.jai.PerspectiveTransform  
Concatenates this transform with a translation transformation.

**translate(double, double)** - Method in class javax.media.jai.TiledImageGraphics

**translate(double, double)** - Method in class javax.media.jai.RenderableGraphics

**translate(int, int)** - Method in class javax.media.jai.GraphicsJAI  
See comments in java.awt.Graphics2D.

**translate(int, int)** - Method in class javax.media.jai.TiledImageGraphics

**translate(int, int)** - Method in class javax.media.jai.RenderableGraphics

**TranslateDescriptor** - class javax.media.jai.operator.TranslateDescriptor.  
An OperationDescriptor describing the "Translate" operation.

**TranslateDescriptor()** - Constructor for class javax.media.jai.operator.TranslateDescriptor  
Constructor.

**TranslatePropertyGenerator** - class javax.media.jai.operator.TranslatePropertyGenerator.

This property generator computes the properties for the operation "Translate" dynamically.

**TranslatePropertyGenerator()** - Constructor for class javax.media.jai.operator.TranslatePropertyGenerator  
Constructor.

**transparency** - Variable in class javax.media.jai.FloatDoubleColorModel

**transparency** - Variable in class com.sun.media.jai.codec.PNGEncodeParam.Palette

**transparency** - Variable in class com.sun.media.jai.codec.PNGEncodeParam.Gray

**transparency** - Variable in class com.sun.media.jai.codec.PNGEncodeParam.RGB

**transparencySet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**TransposeDescriptor** - class javax.media.jai.operator.TransposeDescriptor.

An OperationDescriptor describing the "Transpose" operation.

**TransposeDescriptor()** - Constructor for class javax.media.jai.operator.TransposeDescriptor  
Constructor.

**TransposePropertyGenerator** - class javax.media.jai.operator.TransposePropertyGenerator.

This property generator computes the properties for the operation "Transpose" dynamically.

**TransposePropertyGenerator()** - Constructor for class javax.media.jai.operator.TransposePropertyGenerator  
Constructor.

**transX** - Variable in class javax.media.jai.ScaleOpImage

The horizontal translation factor

**transXRational** - Variable in class javax.media.jai.ScaleOpImage

**transXRationalDenom** - Variable in class javax.media.jai.ScaleOpImage

**transXRationalNum** - Variable in class javax.media.jai.ScaleOpImage

**transY** - Variable in class javax.media.jai.ScaleOpImage

The vertical translation factor

**transYRational** - Variable in class javax.media.jai.ScaleOpImage

**transYRationalDenom** - Variable in class javax.media.jai.ScaleOpImage

**transYRationalNum** - Variable in class javax.media.jai.ScaleOpImage

**type** - Variable in class javax.media.jai.ROIShape.PolyShape

The type of polygon.

**type** - Variable in class com.sun.media.jai.codec.TIFFField

The tag type.

---

## U

**UNCOPIED** - Static variable in class javax.media.jai.RasterFormatTag

**UNCOPIED** - Static variable in class javax.media.jai.RasterAccessor

Flag indicating data is raster's data.

**UNEXPANDED** - Static variable in class javax.media.jai.RasterAccessor

Flag indicating ColorModel info should be ignored

**unregisterCIF(String, String, CollectionImageFactory)** - Method in class javax.media.jai.OperationRegistry

Unregisters a CIF from a particular product and operation.

**unregisterCodec(String)** - Static method in class com.sun.media.jai.codec.ImageCodec

Unregisters the ImageCodec object currently responsible for handling the named format.

**unregisterCRIF(String, ContextualRenderedImageFactory)** - Method in class javax.media.jai.OperationRegistry

Unregisters a CRIF from a particular operation.

**unregisterOperationDescriptor(String)** - Method in class javax.media.jai.OperationRegistry

Unregisters an OperationDescriptor from the registry.

**unregisterRIF(String, String, RenderedImageFactory)** - Method in class javax.media.jai.OperationRegistry

Unregisters a RIF from a particular product and operation.

**unsetBackground()** - Method in class com.sun.media.jai.codec.PNGEncodeParam

Suppresses the 'bKGD' chunk from being output.

**unsetBackground()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Palette

Suppresses the 'bKGD' chunk from being output.

**unsetBackground()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Gray  
Suppresses the 'bKGD' chunk from being output.

**unsetBackground()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.RGB  
Suppresses the 'bKGD' chunk from being output.

**unsetBitDepth()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Suppresses the setting of the bit depth of a grayscale image.

**unsetBitShift()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Gray  
Suppresses the setting of the bit shift of a grayscale image.

**unsetChromaticity()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Suppresses the 'cHRM' chunk from being output.

**unsetCIFPreference(CollectionImageFactory, CollectionImageFactory)** - Method in class javax.media.jai.OperationGraph  
Removes a preference between two CIFs.

**unsetCIFPreference(String, String, CollectionImageFactory, CollectionImageFactory)** - Method in class javax.media.jai.OperationRegistry  
Removes a preference between two CIFs within the same product.

**unsetCompressedText()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Suppresses the 'zTXt' chunk from being output.

**unsetGamma()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Suppresses the 'gAMA' chunk from being output.

**unsetICCProfileData()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Suppresses the 'iCCP' chunk from being output.

**unsetImageBounds()** - Method in class javax.media.jai.ImageLayout  
Marks the parameters dealing with the image bounds (minX, minY, width, and height) as being invalid.

**unsetModificationTime()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Suppresses the 'tIME' chunk from being output.

**unsetPalette()** - Method in class com.sun.media.jai.codec.PNGEncodeParam.Palette  
Suppresses the 'PLTE' chunk from being output.

**unsetPaletteHistogram()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Suppresses the 'hIST' chunk from being output.

**unsetPhysicalDimension()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Suppresses the 'pHYS' chunk from being output.

**unsetPreference(String, String)** - Method in class javax.media.jai.ProductOperationGraph  
Removes a preference between two products.

**unsetProductPreference(String, String, String)** - Method in class javax.media.jai.OperationRegistry  
Removes a preference between two products registered under a common OperationDescriptor.

**unsetRIFPreference(RenderedImageFactory, RenderedImageFactory)** - Method in class javax.media.jai.OperationGraph  
Removes a preference between two RIFs.

**unsetRIFPreference(String, String, RenderedImageFactory, RenderedImageFactory)** - Method in class javax.media.jai.OperationRegistry  
Removes a preference between two RIFs within the same product.

**unsetSignificantBits()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Suppresses the 'sBIT' chunk from being output.

**unsetSRGBIntent()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Suppresses the 'sRGB' chunk from being output.

**unsetSuggestedPalette()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Suppresses the 'sPLT' chunk from being output.

**unsetText()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Suppresses the 'tEXt' chunk from being output.

**unsetTileLayout()** - Method in class javax.media.jai.ImageLayout  
Marks the parameters dealing with the tile layout (tileGridXOffset, tileGridYOffset, tileWidth, and tileHeight) as being invalid.

**unsetTransparency()** - Method in class com.sun.media.jai.codec.PNGEncodeParam  
Suppresses the 'tRNS' chunk from being output.

**unsetValid(int)** - Method in class javax.media.jai.ImageLayout  
Clears selected bits of the valid bitmask.

**UntiledOpImage** - class javax.media.jai.UntiledOpImage.  
A general class for single-source operations in which the values of all pixels in the source image contribute to the value of each pixel in the destination image.

**UntiledOpImage(RenderedImage, TileCache, ImageLayout)** - Constructor for class javax.media.jai.UntiledOpImage  
Constructs an UntiledOpImage.

**update(Graphics)** - Method in class javax.media.jai.widget.ImageCanvas  
There is no need to erase prior to drawing, so we override the default update method to simply call paint().

**updateDrag(Point)** - Method in class javax.media.jai.widget.ScrollingImagePanel  
Called for each point of a mouse drag.

**upSampler** - Variable in class javax.media.jai.ImagePyramid  
 The operation chain used to derive the higher resolution images.

**URLDescriptor** - class javax.media.jai.operator.URLDescriptor.  
 An OperationDescriptor describing the "URL" operation.

**URLDescriptor()** - Constructor for class javax.media.jai.operator.URLDescriptor  
 Constructor.

**useInterlacing** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**userExponent** - Variable in class com.sun.media.jai.codec.PNGDecodeParam

---

## V

**validateArguments(ParameterBlock, StringBuffer)** - Method in interface javax.media.jai.OperationDescriptor  
 Returns true if this operation is capable of handling the input rendered source(s) and/or parameter(s) specified in the ParameterBlock, or false otherwise, in which case an explanatory message may be appended to the StringBuffer.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.OperationDescriptorImpl  
 Returns true if this operation supports the rendered mode, and is capable of handling the input arguments for the rendered mode.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.XorConstDescriptor  
 Validates the input source and parameter.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.CompositeDescriptor  
 Validates the input sources and parameters.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.CropDescriptor  
 Validates the input source and parameters in the rendered mode.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.PeriodicShiftDescriptor  
 Validates the input parameters.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.BandSelectDescriptor  
 Validates the input source and parameters.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.AndConstDescriptor  
 Validates the input source and parameter.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.AddConstToCollectionDescriptor  
 Validates input source and parameter.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.OrConstDescriptor  
 Validates the input source and parameter.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.BandCombineDescriptor  
 Validates the input source and parameters.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.MatchCDFDescriptor  
 Validates the input sources and parameter.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.OrderedDitherDescriptor  
 Validates the input source and parameters.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.DFTDescriptor  
 Validates the input source and parameters.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.PiecewiseDescriptor  
 Validates the input source and parameter.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.IDFTDescriptor  
 Validates the input source and parameters.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.EncodeDescriptor  
 Validates the input source and parameters.

**validateArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.FileStoreDescriptor  
 Validates the input source and parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.OperationDescriptorImpl  
 Returns true if this operation is capable of handling the input parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.RenderableDescriptor  
 Validates input parameters in the renderable layer.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.GradientMagnitudeDescriptor  
 Validates the input parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.BorderDescriptor  
 Validates input parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.ThresholdDescriptor  
 Validates input parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.SubtractFromConstDescriptor  
 Validates the input parameter.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.SubtractConstDescriptor  
Validates the input parameter.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.ClampDescriptor  
Validates the input parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.FileLoadDescriptor  
Validates the input parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.BoxFilterDescriptor

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.IIPResolutionDescriptor  
Validates the input parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.MultiplyConstDescriptor  
Validates the input parameter.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.ConstantDescriptor  
Validates the input parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.AddConstDescriptor  
Validates the input parameter.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.AffineDescriptor  
Validates the input parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.DivideByConstDescriptor  
Validates the input parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.RescaleDescriptor  
Validates the input parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.IIPDescriptor  
Validates the input parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.DivideIntoConstDescriptor  
Validates the input parameters.

**validateParameters(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.ScaleDescriptor  
Validates the input parameters.

**validateRenderableArguments(ParameterBlock, StringBuffer)** - Method in interface javax.media.jai.OperationDescriptor  
Returns true if this operation is capable of handling the input renderable source(s) and/or parameter(s) specified in the ParameterBlock, or false otherwise, in which case an explanatory message may be appended to the StringBuffer.

**validateRenderableArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns true if this operation supports the renderable mode, and is capable of handling the input arguments for the renderable mode.

**validateRenderableArguments(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.CropDescriptor  
Validates the input source and parameters in the renderable mode.

**validateRenderableSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns true if this operation supports the renderable mode, and is capable of handling the input source(s) for the renderable mode.

**validateSources(Class[], ParameterBlock, StringBuffer)** - Method in class javax.media.jai.OperationDescriptorImpl  
Validates sources in the ParameterBlock against the sources of the specification.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.OperationDescriptorImpl  
Returns true if this operation supports the rendered mode, and is capable of handling the input source(s) for the rendered mode.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.PolarToComplexDescriptor  
Validates the input sources.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.LookupDescriptor  
Validates the input source.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.MagnitudeDescriptor  
Validates the input source.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.AndDescriptor  
Validates the input sources.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.NotDescriptor  
Validates the input source.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.PhaseDescriptor  
Validates the input source.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.OverlayDescriptor  
Validates the input sources.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.MultiplyComplexDescriptor  
Validates the input sources.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.MagnitudeSquaredDescriptor  
Validates the input source.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.AddCollectionDescriptor  
Validates input source collection.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.ConjugateDescriptor  
Validates the input sources.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.DivideComplexDescriptor  
Validates the input sources.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.XorDescriptor  
Validates the input sources.

**validateSources(ParameterBlock, StringBuffer)** - Method in class javax.media.jai.operator.OrDescriptor  
Validates the input sources.

**validMask** - Variable in class javax.media.jai.ImageLayout  
The 'or'-ed together valid bitmasks.

**VAR\_COLOR\_MODEL** - Static variable in class javax.media.jai.RemoteImage  
Index of local variable.

**VAR\_HEIGHT** - Static variable in class javax.media.jai.RemoteImage  
Index of local variable.

**VAR\_MIN\_X** - Static variable in class javax.media.jai.RemoteImage  
Index of local variable.

**VAR\_MIN\_Y** - Static variable in class javax.media.jai.RemoteImage  
Index of local variable.

**VAR\_SAMPLE\_MODEL** - Static variable in class javax.media.jai.RemoteImage  
Index of local variable.

**VAR\_SOURCES** - Static variable in class javax.media.jai.RemoteImage  
Index of local variable.

**VAR\_TILE\_GRID\_X\_OFFSET** - Static variable in class javax.media.jai.RemoteImage  
Index of local variable.

**VAR\_TILE\_GRID\_Y\_OFFSET** - Static variable in class javax.media.jai.RemoteImage  
Index of local variable.

**VAR\_TILE\_HEIGHT** - Static variable in class javax.media.jai.RemoteImage  
Index of local variable.

**VAR\_TILE\_WIDTH** - Static variable in class javax.media.jai.RemoteImage  
Index of local variable.

**VAR\_WIDTH** - Static variable in class javax.media.jai.RemoteImage  
Index of local variable.

**vectorize(RenderedImage)** - Static method in class javax.media.jai.OpImage  
A utility method used by constructors to store sources in a Vector.

**vectorize(RenderedImage, RenderedImage)** - Static method in class javax.media.jai.OpImage  
A utility method used by constructors to store sources in a Vector.

**vectorize(RenderedImage, RenderedImage, RenderedImage)** - Static method in class javax.media.jai.OpImage  
A utility method used by constructors to store sources in a Vector.

**vectorToIntArray(Vector)** - Method in class javax.media.jai.ROIShape.PolyShape  
Convert a Vector of Integers to an array of ints.

**vectorToStrings(Vector)** - Static method in class com.sun.media.jai.codec.ImageCodec

**version** - Variable in class com.sun.media.jai.codec.BMPEncodeParam

**VERSION\_2** - Static variable in class com.sun.media.jai.codec.BMPEncodeParam  
Constant for BMP version 2.

**VERSION\_3** - Static variable in class com.sun.media.jai.codec.BMPEncodeParam  
Constant for BMP version 3.

**VERSION\_4** - Static variable in class com.sun.media.jai.codec.BMPEncodeParam  
Constant for BMP version 4.

**ViewportListener** - interface javax.media.jai.widget.ViewportListener.  
An interface used by the ScrollingImagePanel class to inform listeners of the current viewable area of the image.

**viewportListeners** - Variable in class javax.media.jai.widget.ScrollingImagePanel  
Vector of ViewportListeners.

**volatilePropertyInfo** - Variable in class javax.media.jai.RenderedOp  
Cache of information in "thePropertySource" which is lost in the serialization/deserialization process.

**volatilePropertyInfo** - Variable in class javax.media.jai.RenderableOp  
Cache of information in "thePropertySource" which is lost in the serialization/deserialization process.

**vSamp** - Variable in class com.sun.media.jai.codec.JPEGEncodeParam

---

## W

**warp** - Variable in class javax.media.jai.WarpOpImage

The Warp object describing the backwards pixel map.

**Warp** - class javax.media.jai.Warp.

A description of an image warp.

**Warp()** - Constructor for class javax.media.jai.Warp

Default constructor.

**WarpAffine** - class javax.media.jai.WarpAffine.

A description of an Affine warp.

**WarpAffine(AffineTransform)** - Constructor for class javax.media.jai.WarpAffine

Constructs a WarpAffine with pre- and post-scale factors of 1.

**WarpAffine(AffineTransform, float, float, float, float)** - Constructor for class javax.media.jai.WarpAffine

Constructs a WarpAffine with a given transform mapping destination pixels into source space.

**WarpAffine(float[], float[])** - Constructor for class javax.media.jai.WarpAffine

Constructs a WarpAffine with pre- and post-scale factors of 1.

**WarpAffine(float[], float[], float, float, float, float)** - Constructor for class javax.media.jai.WarpAffine

Constructs a WarpAffine with a given transform mapping destination pixels into source space.

**WarpCubic** - class javax.media.jai.WarpCubic.

A cubic-based description of an image warp.

**WarpCubic(float[], float[])** - Constructor for class javax.media.jai.WarpCubic

Constructs a WarpCubic with pre- and post-scale factors of 1.

**WarpCubic(float[], float[], float, float, float, float)** - Constructor for class javax.media.jai.WarpCubic

Constructs a WarpCubic with a given transform mapping destination pixels into source space.

**WarpDescriptor** - class javax.media.jai.operator.WarpDescriptor.

An OperationDescriptor describing the "Warp" operation.

**WarpDescriptor()** - Constructor for class javax.media.jai.operator.WarpDescriptor

Constructor.

**WarpGeneralPolynomial** - class javax.media.jai.WarpGeneralPolynomial.

A general polynomial-based description of an image warp.

**WarpGeneralPolynomial(float[], float[])** - Constructor for class javax.media.jai.WarpGeneralPolynomial

Constructs a WarpGeneralPolynomial with pre- and post-scale factors of 1.

**WarpGeneralPolynomial(float[], float[], float, float, float, float)** - Constructor for class

javax.media.jai.WarpGeneralPolynomial

Constructs a WarpGeneralPolynomial with a given transform mapping destination pixels into source space.

**WarpGrid** - class javax.media.jai.WarpGrid.

A regular grid-based description of an image warp.

**WarpGrid(int, int, int, int, int, int, float[])** - Constructor for class javax.media.jai.WarpGrid

Constructs a WarpGrid with a given grid-based transform mapping destination pixels into source space.

**WarpGrid(Warp, int, int, int, int, int, int)** - Constructor for class javax.media.jai.WarpGrid

Constructs a WarpGrid object by sampling the displacements given by another Warp object of any kind.

**WarpOpImage** - class javax.media.jai.WarpOpImage.

A general implementation of image warping, and a superclass for other geometric image operations.

**WarpOpImage(RenderedImage, BorderExtender, TileCache, ImageLayout, Warp, Interpolation, boolean)** -

Constructor for class javax.media.jai.WarpOpImage

Constructs a WarpOpImage.

**WarpPerspective** - class javax.media.jai.WarpPerspective.

A description of a perspective (projective) warp.

**WarpPerspective(PerspectiveTransform)** - Constructor for class javax.media.jai.WarpPerspective

Constructs a WarpPerspective with a given transform mapping destination pixels into source space.

**warpPoint(int, int, float[])** - Method in class javax.media.jai.Warp

Computes the source subpixel position for a given destination pixel.

**warpPoint(int, int, int, int, int[])** - Method in class javax.media.jai.Warp

Computes the source subpixel position for a given destination pixel.

**WarpPolynomial** - class javax.media.jai.WarpPolynomial.

A polynomial-based description of an image warp.

**WarpPolynomial(float[], float[])** - Constructor for class javax.media.jai.WarpPolynomial

Constructs a WarpPolynomial with pre- and post-scale factors of 1.

**WarpPolynomial(float[], float[], float, float, float, float)** - Constructor for class javax.media.jai.WarpPolynomial

Constructs a WarpPolynomial with a given transform mapping destination pixels into source space.

**WarpPropertyGenerator** - class javax.media.jai.operator.WarpPropertyGenerator.

This property generator computes the properties for the operation "Warp" dynamically.

**WarpPropertyGenerator()** - Constructor for class javax.media.jai.operator.WarpPropertyGenerator

Constructor.

**WarpQuadratic** - class javax.media.jai.WarpQuadratic.

A quadratic-based description of an image warp.

**WarpQuadratic(float[], float[])** - Constructor for class javax.media.jai.WarpQuadratic  
Constructs a WarpQuadratic with pre- and post-scale factors of 1.

**WarpQuadratic(float[], float[], float, float, float, float)** - Constructor for class javax.media.jai.WarpQuadratic  
Constructs a WarpQuadratic with a given transform mapping destination pixels into source space.

**warpRect(int, int, int, int, float[])** - Method in class javax.media.jai.Warp  
Computes the source subpixel positions for a given rectangular destination region.

**warpRect(int, int, int, int, int, int, int[])** - Method in class javax.media.jai.Warp  
Computes the source subpixel positions for a given rectangular destination region.

**warpSparseRect(int, int, int, int, int, int, float[])** - Method in class javax.media.jai.Warp  
This method is abstract in this class and must be provided in concrete subclasses.

**warpSparseRect(int, int, int, int, int, int, float[])** - Method in class javax.media.jai.WarpQuadratic  
Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period.

**warpSparseRect(int, int, int, int, int, int, float[])** - Method in class javax.media.jai.WarpAffine  
Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period.

**warpSparseRect(int, int, int, int, int, int, float[])** - Method in class javax.media.jai.WarpPerspective  
Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period.

**warpSparseRect(int, int, int, int, int, int, float[])** - Method in class javax.media.jai.WarpGrid  
Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period.

**warpSparseRect(int, int, int, int, int, int, float[])** - Method in class javax.media.jai.WarpCubic  
Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period.

**warpSparseRect(int, int, int, int, int, int, float[])** - Method in class javax.media.jai.WarpGeneralPolynomial  
Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period.

**warpSparseRect(int, int, int, int, int, int, int, int[])** - Method in class javax.media.jai.Warp  
Computes the source subpixel positions for a given rectangular destination region, subsampled with an integral period.

**weakThis** - Variable in class javax.media.jai.PlanarImage  
A WeakReference to this image.

**width** - Variable in class javax.media.jai.ImageLayout  
The image's width.

**width** - Variable in class javax.media.jai.PlanarImage  
The image's width in pixels.

**width** - Variable in class javax.media.jai.Interpolation  
The width of the interpolation kernel in pixels.

**width** - Variable in class javax.media.jai.MultiResolutionRenderableImage  
The width in Renderable coordinates.

**width** - Variable in class javax.media.jai.KernelJAI  
The width of the kernel.

**WIDTH\_MASK** - Static variable in class javax.media.jai.ImageLayout  
A bitmask to specify the validity of width.

**wrapInputStream(InputStream, boolean)** - Static method in class com.sun.media.jai.codec.SeekableStream  
Returns a SeekableStream that will read from a given InputStream, optionally including support for seeking backwards.

**wrapRenderableImage(RenderableImage)** - Static method in class javax.media.jai.RenderableImageAdapter  
Adapts a RenderableImage into a RenderableImageAdapter.

**wrapRenderedImage(RenderedImage)** - Static method in class javax.media.jai.PlanarImage  
Wraps an arbitrary RenderedImage to produce a PlanarImage.

**writableBounds** - Variable in class javax.media.jai.WarpOpImage  
The writable boundary of this image.

**WritableRandomIter** - interface javax.media.jai.iterator.WritableRandomIter.  
An iterator that allows random read/write access to any sample within its bounding rectangle.

**WritableRasterJAI** - class javax.media.jai.WritableRasterJAI.

**WritableRasterJAI(SampleModel, DataBuffer, Rectangle, Point, WritableRaster)** - Constructor for class javax.media.jai.WritableRasterJAI

**WritableRectIter** - interface javax.media.jai.iterator.WritableRectIter.  
An iterator for traversing a read/write image in top-to-bottom, left-to-right order.

**WritableRenderedImageAdapter** - class javax.media.jai.WritableRenderedImageAdapter.  
A PlanarImage wrapper for a WritableRenderedImage.

**WritableRenderedImageAdapter(WritableRenderedImage)** - Constructor for class javax.media.jai.WritableRenderedImageAdapter  
Constructs a WritableRenderedImageAdapter.

**WritableRookIter** - interface javax.media.jai.iterator.WritableRookIter.  
An iterator for traversing a read/write image using arbitrary up-down and left-right moves.

**writeExternal(ObjectOutput)** - Method in class javax.media.jai.OperationRegistry  
Saves the contents of the registry in the format described for the writeToStream method.

**writeImageOnly** - Variable in class com.sun.media.jai.codec.JPEGEncodeParam

**writeJFIFHeader** - Variable in class com.sun.media.jai.codec.JPEGEncodeParam

**writeObject(ObjectOutputStream)** - Method in class javax.media.jai.ImageLayout  
Serialize the ImageLayout.

**writeObject(ObjectOutputStream)** - Method in class javax.media.jai.RenderedOp  
Serializes the RenderedOp.

**writeObject(ObjectOutputStream)** - Method in class javax.media.jai.RenderableOp  
Serialize the RenderableOp.

**writeObject(ObjectOutputStream)** - Method in class javax.media.jai.ROI  
Serialize the ROI.

**writeObject(ObjectOutputStream)** - Method in class javax.media.jai.MultiResolutionRenderableImage  
Serialize the MultiResolutionRenderableImage.

**writeObject(ObjectOutputStream)** - Method in class javax.media.jai.LookupTableJAI  
Serialize the LookupTableJAI.

**writeObject(ObjectOutputStream)** - Method in class javax.media.jai.ROIShape  
Serialize the ROIShape.

**writers** - Variable in class javax.media.jai.TiledImage  
The number of writers of each tile; -1 indicates a locked tile.

**writeTablesOnly** - Variable in class com.sun.media.jai.codec.JPEGEncodeParam

**writeTiled** - Variable in class com.sun.media.jai.codec.TIFFEncodeParam

**writeToStream(OutputStream)** - Method in class javax.media.jai.OperationRegistry  
Writes out the contents of the OperationRegistry to a stream.

---

## X

**x** - Variable in class javax.media.jai.ROIShape.PolyShape.PolyEdge  
X coordindate of intersection of edge with current scanline.

**xCoeffs** - Variable in class javax.media.jai.WarpPolynomial  
An array of coefficients that maps a destination point to the source's X coordinate.

**xCoeffsHelper(AffineTransform)** - Static method in class javax.media.jai.WarpAffine

**xEnd** - Variable in class javax.media.jai.WarpGrid

**xNumCells** - Variable in class javax.media.jai.WarpGrid

**XOR\_MODE** - Static variable in class javax.media.jai.TiledImageGraphics

**XORColor** - Variable in class javax.media.jai.TiledImageGraphics

**XorConstDescriptor** - class javax.media.jai.operator.XorConstDescriptor.  
An `OperationDescriptor` describing the "XorConst" operation.

**XorConstDescriptor()** - Constructor for class javax.media.jai.operator.XorConstDescriptor  
Constructor.

**XorDescriptor** - class javax.media.jai.operator.XorDescriptor.  
An `OperationDescriptor` describing the "Xor" operation.

**XorDescriptor()** - Constructor for class javax.media.jai.operator.XorDescriptor  
Constructor.

**xOrigin** - Variable in class javax.media.jai.KernelJAI  
The X coordinate of the key element.

**xPeriod** - Variable in class javax.media.jai.StatisticsOpImage  
The horizontal sampling rate.

**xStart** - Variable in class javax.media.jai.WarpGrid

**xStart** - Variable in class javax.media.jai.StatisticsOpImage  
The X coordinate of the initial sample.

**xStep** - Variable in class javax.media.jai.WarpGrid

**XtoTileX(int)** - Method in class javax.media.jai.widget.ImageCanvas

**XToTileX(int)** - Method in class javax.media.jai.PlanarImage  
Converts a pixel's X coordinate into a horizontal tile index.

**XToTileX(int, int, int)** - Static method in class javax.media.jai.PlanarImage  
Converts a pixel's X coordinate into a horizontal tile index relative to a given tile grid layout specified by its X offset and tile width.

**xWarpPos** - Variable in class javax.media.jai.WarpGrid

---

## Y

**yCoeffs** - Variable in class javax.media.jai.WarpPolynomial

An array of coefficients that maps a destination point to the source's Y coordinate.

**yCoeffsHelper(AffineTransform)** - Static method in class javax.media.jai.WarpAffine

**yEnd** - Variable in class javax.media.jai.WarpGrid

**yNumCells** - Variable in class javax.media.jai.WarpGrid

**yOrigin** - Variable in class javax.media.jai.KernelJAI

The Y coordinate of the key element.

**yPeriod** - Variable in class javax.media.jai.StatisticsOpImage

The vertical sampling rate.

**yStart** - Variable in class javax.media.jai.WarpGrid

**yStart** - Variable in class javax.media.jai.StatisticsOpImage

The Y coordinate of the initial sample.

**yStep** - Variable in class javax.media.jai.WarpGrid

**YtoTileY(int)** - Method in class javax.media.jai.widget.ImageCanvas

**YToTileY(int)** - Method in class javax.media.jai.PlanarImage

Converts a pixel's Y coordinate into a vertical tile index.

**YToTileY(int, int, int)** - Static method in class javax.media.jai.PlanarImage

Converts a pixel's Y coordinate into a vertical tile index relative to a given tile grid layout specified by its Y offset and tile height.

**yWarpPos** - Variable in class javax.media.jai.WarpGrid

---

## Z

**zeroLink** - Variable in class javax.media.jai.PartialOrderNode

A link to another node with 0 in-degree, or null.

**zText** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

**zTextSet** - Variable in class com.sun.media.jai.codec.PNGEncodeParam

---

< A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
